I have only to apologise for the length of this letter, and to add that, if any of my suggestions should lead to an improvement in the method adopted for investigating the truths of this important science, my object will have been fully accomplished.

I am, etc.,

GEORGE F. BURDER, M.D.

Clifton, Oct. 20th, 1853.

[Improvements in the Weekly Table are at present under the consideration of the Meteorological Observers. We invite all who have suggestions to make to forward them now, not for publication, but for our guidance. Editor.]

OBSERVATIONS ON OZONE.

LETTER FROM DR. JOHN DREW TO THE EDITOR.

SIR,—As you take an interest in ozone observations, and many of your readers have engaged to take part in those which will be forwarded to Dr. Schönbein through me, perhaps you would kindly inform them that Mr. Cox will be prepared in about three weeks to supply Schönbein's ozonometer on application. We propose to commence simultaneous observations all over Great Britain on January 1st, 1854.

In a letter just received from Dr. Schönbein, he says,

"I am indeed very glad you have so well succeeded in engaging a large number of gentlemen to make regular ozonometric observations; and I am inclined to believe that by so doing, you have rendered a valuable service, not only to the physical but medical and physiological sciences.

"Having of late been in Vienna, and seen there M. Kreil, the head of the meteorological stations being established at very different points of the Austrian empire, I induced that gentleman to introduce my ozonometer in the observatories placed under his guidance, and by this time the observations will have begun to be made from the Turkish to the Italian frontiers, in the lowlands as well as in the highest Alpine regions."

The Astronomer Royal will obtain observations in conjunction with the elaborate system of meteorological registration kept at Greenwich Observatory.

I am, etc.,

JOHN DREW.

Southampton, October 17th, 1853.

ASSOCIATION STATISTICS.

LETTER TO THE EDITOR.

SIR,—Allow me to suggest to you the publication monthly of the names of new members, and a statement of the amount of subscriptions received.

I am, etc.,

November 1st, 1853.

[The General Secretary alone possesses the means for the compilation of such statistics: but as interest and endeavour, with his aid, to give as much information on the topics referred to. Editor.]

MEDICO-METEOROLOGICAL OBSERVATIONS

Taken for the Association Medical Journal.

No. V.—WEEK ENDING 29TH OCTOBER 1853.

WAKEFIELD. Lat. 53.40.50 N.; Lon. 1.30.26 W.; Height of Cistern of Barometer above the Mean Sea Level, 115 feet.

NEWS AND TOPICS OF THE DAY.

[Continued from page 960.]

CENTRAL CRIMINAL COURT. Oct. 24. (Before the Recorder.) Henry Hamilton, described as a surgeon, surrendered to take his trial for an assault upon Elizabeth Brown. The defendant, who was an advertising doctor, practised in King William Street; Strand; and the prosecutrix, a young woman twenty-two years old, went to consult him; and according to her evidence, he told her she was in the family way, and then made disgusting overtures, and proceeded to commit acts of indecency on her. The Recorder having summed up, the jury, after a short deliberation, returned a verdict of *Guilty*.

On October 20th, the prisoner was brought up to receive judgment.

Mr. Parry, on behalf of the prosecution, said that he had to call to the notice of the Court the fact that the prisoner was a complete impostor; the advertisements put forth by him were a false pretence, as he styled himself Dr. Hamilton, of the Royal College of Surgeons, when he was not a surgeon, neither was that his name.

Four ladies, and ten highly respectable gentlemen gave the prisoner a good character: but in cross examination they admitted that they did not know him to be an "advertising surgeon".

The prisoner said the reason he practised under the name of Hamilton was that Dr. Hamilton was formerly his partner.

The Recorder, in passing sentence, said that although the circumstances of the case surrounded it with difficulty, and made it one of an aggravated character, the jury could not have come to any other conclusion than they did. It was a most gross and serious matter: for a woman, when she placed herself in the hands of a medical man in such circumstances, was in a measure defenceless. It was of the utmost importance that women who were compelled to seek advice, and expose the maladies under which they laboured, should not be in any way deterred from doing so by the fear that their position would be abused and taken advantage of. He should not deal harshly with him because he was not a regular practitioner, nor because he was an advertising doctor, but for the reason he had stated. He then sentenced him to twelve months' imprisonment in the House of Correction. (Abridged from the *Times* of October 25 and 27.)

MYSTERIOUS AFFAIR AT THE HYDROPATHIC ESTABLISHMENT AT MALVERN. The *Sun* of October 29th contains an account of the circumstances attending the commission of a robbery from the apartments of a gentleman visiting Malvern. The following is an abridgment of the statement:—About the middle of July last, Mr. S. Kelsell, a gentleman of independent property, placed himself under the care of Dr. Wilson, a hydropathist at Malvern. Among the servants at the place was a man named David Filtness, with whose wife Mr. Kelsell is said to have made a pleasure excursion of a fortnight in the country, in the early part of September. Immediately upon Mr. Kelsell's return, Filtness absconded, taking with him £246 in gold and notes, with a diamond ring, and other property. In the early part of October, Filtness rendered himself up to justice, and has been examined before the magistrates at Malvern. He stated, on his examination, that the money was given to him by Mr. Kelsell for consenting to the commission of an abominable offence; which was at once denied by Mr. Kelsell. He has been committed for trial at the next Worcester Assizes. The accused attempted to implicate many in his alleged criminal practices.

EDINBURGH CHAIR OF NATURAL HISTORY: DIFFICULTIES IN THE WAY. It appears that Mr. Jameson's offer to resign his appointments is conditional upon the Town Council appointing his nephew his successor as Keeper of the Museum. Though the Town Council are patrons of the office of keeper, the Crown has the patronage of the Chair of Natural History. The two appointments ought to be, and always have been, held by the same individual, and if they are now to be separated, it is not likely that Professor Edward Forbes, or any other man of equal eminence, will accept of the Chair of Natural History. Apart from the division of emoluments, the irksomeness to a professor of having another party placed over the objects with which his lectures have to be illustrated seems quite enough to create many inconveniences and hindrances to efficiency. During the ensuing session, Dr. Traill, Professor of Medical Jurisprudence, is to give the course of natural history, the incumbent being disqualified through age and infirmity. We trust that a liberal

pension may be conferred by Government upon the retiring professor, in testimony of the sense which is universally entertained of the great and long-continued services which he has rendered to science; and we also hope that the character of this important chair may not be impaired by its partition from the keepership.

GIFT TO THE "GAZETTE DES HÔPITAUX." A subscriber for twenty-five years to the *Gazette des Hôpitaux*, as a return for the instruction derived from its pages, has presented to its proprietors the sum of 10,000 francs (£400), on the following conditions:—1st. That his name be concealed. 2d. That 3,000 francs be given to the authors of the most useful and practical papers inserted in its pages, and 7,000 francs to diminish the subscription of those who could not afford to pay the entire sum. The proprietors of the *Gazette* now offer to give their journal for twenty francs to 200; for fifteen francs to 200, and for ten francs to 100 subscribers.

CANADA MEDICAL JOURNAL: THE ARREARS OF ITS SUBSCRIBERS. The editor of the *Canada Medical Journal* has an abundance of readers who have promised to pay, but too few who really perform this promise. In his February number, he thus brings matters to a crisis:—

"As the subscribers have not paid up in the manner that we anticipated, we shall not issue the first number of the second volume until April, when it will appear at the same time with the number for that month. We have been induced to adopt this measure, from the difficulty we have experienced in convincing our readers that, to support a medical journal, money is really necessary; and many of them may think that, because the monthly visit of the Journal brings them no greater trouble than to send to the post-office for it, or expense than to pay the postage, that the publication entails very little expense or trouble upon its managers. We beg to disabuse their minds on this point. Journalism is both expensive and troublesome; and, though we cheerfully undergo the latter, we have no idea of encountering the former. In such matters, plain speaking is always best; and we give our proposal to the profession as follows: We will go on with the *Canada Medical Journal*, if you pay your subscriptions before the 1st of next April; if you do not, the Journal must cease. Our subscription list shows that the revenue of the Journal, if paid up regularly, would amply cover all expenses, and even admit of the editors illustrating some of the articles with wood-cuts, etc."

SMALL POX LEGISLATION IN CANADA. At the close of the session of the Parliament of Lower Canada, the Governor-General sanctioned a bill, intitled "An Act to restrain the injurious practice of inoculating with the small pox." The preamble and enacting clause of the bill read thus: "Whereas it is highly expedient to restrain the injurious practice of inoculating with the natural small pox (*variola*); Be it enacted, etc., That any person who shall produce or attempt to produce, by inoculation with variolous matter, or by wilful exposure to variolous matter, or to any matter, article, or thing, impregnated with variolous matter, or wilfully by any means whatsoever, the disease of small pox in any person in this province, shall be liable to be proceeded against and convicted summarily before any two justices; and for every such offence shall, upon conviction, be imprisoned for any term not exceeding one month."

EPIDEMIOLOGICAL SOCIETY. Meetings for 1853-4. In 1853: Mondays, Nov. 7th, Dec. 5th. In 1854: Mondays, Jan. 2nd, Feb. 6th, March 6th, April 3rd, May 1st, June 5th, July 3rd, Aug. 7th. The meetings will be held at half-past 8 p.m., at the house of the Royal Medical and Chirurgical Society, 53 Berners Street.

MEDICAL SOCIETY OF LONDON. The following papers are announced as intended to be read at the ordinary meetings of this society.

Saturday, November 5th. J. R. Cormack, M.D., "On Cholera".

Saturday, November 12th. R. H. Semple, M.D., "On the Pathology and Treatment of Cerebral Diseases."

Monday, November 14th, in the Physiological Section. Edwards Crisp, M.D., "On the Form and Weight of the Heart, the Diameter of the Aorta, and the Size of the Blood-Corpuscles, in the various classes of Vertebrate Animals."

Saturday, November 19th. Haynes Walton, Esq., "On Inflammation of the Eye-Ball, especially that form of it usually called Iritis."

Saturday, November 26th. E. J. T. M.D., "On Metritis."

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XLV.

LONDON: FRIDAY EVENING, NOVEMBER 11, 1853.

NEW SERIES.

FRATERNITY BETWEEN METROPOLITAN AND PROVINCIAL PRACTITIONERS.

TWENTY-ONE years ago, when the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION was founded, there prevailed in the provinces strong feelings of distrust and jealousy of metropolitan physicians and surgeons. In fact, it was in no small degree owing to the arrogance of the London magnates, and to the depreciatory attitude which they assumed towards their provincial brethren, that so many rallied round our Association in its earlier years. The Provincial Association was, in fact, established and originally supported with the view of vindicating, before the world, the highly advanced state of the profession in the provinces, of maintaining its privileges, and securing its progress. These objects have been, all must admit, accomplished in no small degree. The advance of the new institution has been ever onward, in spite of many difficulties and discouragements which have beset its career; and with this prosperity, old jealousies, in place of being fostered, have gradually declined, and may now be truly said to have neither an existence nor an apology. The practitioners of town and country perceiving that by railways, journals, and improved education, their geographical and intellectual distinctions have been swept away, have seen that their true policy is to retire from even the appearance of antagonism, and to unite for mutual counsel and support, in one great fraternal association, in which the rights of all members shall be equal. These were the sentiments expressed by every one present at the dinner of the conjoined committees on Thursday last, and they are, we venture to aver, the sentiments of the five hundred gentlemen who have joined the Association during this year, of hundreds about to join our ranks in January, and also of a vast majority of the original members who, from the causes already stated, were once united to each other by very different bonds from those which now exist—by the necessity for protection, and by the jealousy of those who are now firm friends and active allies.

A great ethical movement is at present going on within our body, which cannot fail, ultimately, to cement together still more firmly than ever all the loyal and honest members of the medical profession. The two fundamental principles upon which the Medico-Ethical Committee of the Association and the Gratuitous Advice Committee of the Metropolitan Branch proceed, are cooperation with each other, and the careful collection and digestion of the opinions and facts supplied by all who are willing to contribute them. In subsequent numbers, we propose to direct attention to the proceedings and aims of the two committees. In the meantime, on their behalf and at their request, we earnestly invite all who have information to give, to forward it freely and early to the respective secretaries. The old jealousies between town and country must be buried in oblivion, since fraternity between metropolitan and provincial practitioners is not only morally right, but is, likewise, the best professional policy. Without this fraternity, the power and influence of the profession can never be increased.

ORIGINAL COMMUNICATIONS.

NOTES ON THE PATHOLOGY AND TREATMENT OF CHOLERA.*

By JOHN ROSE CORMACK, M.D.

The following notes are not offered as a complete paper on cholera; and they are simply intended to present, in a condensed form, the leading pathological and therapeutical opinions adopted by the author, after a careful study of the disease in books, and at the bedside. The views which are unfolded are the same as those which I espoused anonymously in the *London Journal of Medicine* for 1849, and in a speech delivered at the Westminster Medical Society, on October 6th of the same year.

To give some degree of method to the remarks, they are arranged under the following heads:—

- I. MANNER OF STUDYING CHOLERA.
- II. DIAGNOSIS OF CHOLERA.
- III. OBSERVATIONS MADE BY THE AUTHOR DURING PART OF THE EPIDEMIC OF 1848-49.
- IV. PATHOLOGY OF CHOLERA, INCLUDING ITS MORBID ANATOMY.
- V. TREATMENT OF CHOLERA.

I. MANNER OF STUDYING THE DISEASE.

The majority of authors who have treated of cholera, have drawn their descriptions too exclusively from the more appalling forms of the disease, and have too generally spoken of the diarrhoea concurrently abounding, especially at the beginning and at the decline of an outbreak of severe cholera, as if it were a malady different in kind, as well as in degree. To this obvious but common error must, in a great degree, be ascribed the unsatisfactory nature of the literature of cholera, and the perplexing contrariety of opinion which prevails among practitioners as to the pathology of the disease, and its appropriate treatment. The phenomena of aggravated cases, and the appearances found in the bodies of those who died, have unfortunately formed the chief materials out of which theories have been constructed; and the natural history of the disease, the true key to the mystery, has been nearly neglected; or, in other words, adequate attention has not been bestowed upon the natural course of those cases which, from being essentially mild in degree, or in some other way favourably circumstanced, terminate in recovery without much, or without any, medical interference. In all diseases, very much is to be learned by the minute study of simple and uncomplicated cases, which have not been disturbed in their career by any treatment; and assuredly no advance can be made in rational medicine by those who take their notions of what a disease is only from books, or only from their own observation of patients with whom active measures have been adopted. Therapeutical experiments must be jealously corrected by the observation of simple cases, which have been mainly confided to nature; and recoveries must not be promiscuously set down as cures. There are unfortunately some among us very prone to commit this error; while others, by pursuing no plan of treatment upon clear principles, or with the necessary firmness, or with the slight modifications which may be required from day to day, become sceptical of the therapeutical resources of medical science, and yet never suspect that their scepticism is mainly

* The substance of this paper was read before the Medical Society of London on the 6th current.

the fruit of their incapacity to furnish for themselves legitimate data. Cherishing, however, as I do, a strong faith in the efficacy of many of the curative means employed in practice, I equally hold that one of the best ways of learning the skilful use of these means, is patiently to watch and study the phenomena of spontaneous recoveries. It is a species of investigation which is replete with benefits to all concerned. By pursuing it, the practitioner procures and secures for himself a stock of knowledge which neither the theorist of the closet, nor the empiric of the day, can ever wrench from him nor deteriorate; and which will impart to his practice an amount of well founded self-confidence and of success, which could in no other way be obtained.

Numerous illustrations of the truth of these remarks readily suggest themselves; and probably no one has any objection to offer to them, except that they are very prosy and common place. Nevertheless, if we turn to the current medical literature, we find that they are practically disregarded by some of our most ready writers. They are too plain and homely to win the favour of those ambitious men who yearn after brilliant theories, and seek to captivate the world by special systems and new formularies. But while the evils which flow from the want of adequate attention being paid to the natural history of disease are conspicuous, the advantages of this study are equally striking in the improved treatment of many diseases; among which may be mentioned some of the most formidable disorders, such as pneumonia, tuberculosis, syphilis, and fever.

Thousands of cases of scarlet fever recover almost spontaneously, while others are obviously saved by the skilful use of remedies; but, on the other hand, not a few are tremendously rapid in their fatal career, and proclaim to the eye of experience, almost from the moment of seizure, that a sentence of death has gone forth, and that the hours of the victim are few and may be numbered. Now, although epidemics of scarlet fever differ much from one another in severity and in other respects, yet we often meet with the mildest and the most terrible cases occurring simultaneously or consecutively even in the same house. We are taught by the frequency of such occurrences that both classes of cases, though strikingly different in many of their phenomena, are the results of one morbid poison; and that the diversity of effects proceeds not from a diversity of poison, but from a difference in the quantity imbibed, and in the condition of the recipient. It is equally reasonable to regard tractable cholera and intractable cholera as pathologically the same; and therefore of course to include in the same category all the cases which are intermediate between these two extremes. If this rule were adopted, the mortuary statistics of cholera, as published in the newspapers, would be more truthful, and less appalling.

If we hope to learn from nature, we must interrogate her fairly. If we wish to discover the essential character of any epidemic—be it of measles, of scarlatina, of cholera, or of any other disease—we must not only follow the rules which have been above stated, but we must also proceed a step farther. We must observe and study the condition of the whole population during a given period, and within a given district: we must, in particular, trace out and record the characters by which the maladies of all the sick persons are characterised; and we must not begin by adopting an ideal standard of what are the essential features of the disease to be investigated, and then limit our observations to such instances as fall within this ideal boundary. Is it not by adopting foregone conclusions as to the very essence of the questions to be solved, that even good observers have accumulated materials too faulty to be safely used in the construction of opinions? But, however painstaking and conscientious a single observer may be, he cannot singly collect all the materials for a complete history of an epidemic; and this is a fact too commonly forgotten. Isolated observers can do little for epidemiology, compared with what might be accomplished by district societies of medical observation, in which the members adopted by mutual consent

an uniform plan of treatment and of reporting. If such societies were now to be extensively formed and carefully organised, a mass of trustworthy data would be obtained; and there is no other method by which many disputed questions relating to cholera, and epidemics generally, can ever be settled.

Painfully impressed with the imperfections of the following observations, I have ventured to introduce them by these prefatory remarks. My little contribution of facts may be useful apart from all theory; and, while I freely state the opinions which I have formed, I avow with equal frankness my conviction that, notwithstanding all that has been written regarding cholera, sufficient data do not yet exist to entitle any one to feel quite confident that his opinions are built upon an unassailable foundation.

After briefly reciting a chapter from my own experience, I propose to state briefly the opinions which I have been led to adopt, and which I have based upon that experience, in conjunction with a tolerably extensive course of reading upon the subject of cholera.

II. DIAGNOSIS OF CHOLERA.

The diagnosis between English cholera and Asiatic cholera has engaged the attention of many writers; but I agree with Dr. Knox in thinking that it is "useless and impracticable" to discriminate between them. That judicious author well remarks:—"No means of discrimination are generally known, or we should not hear one practitioner saying that he could see no difference in the diseases except in the number of the cases; and another, that he should be of opinion that he had been treating a case of Asiatic cholera, had that disease been present in the country." [KNOX, Alex., M.D., *On Cholera*, Dublin, 1849.] Slight cases of cholera, like slight cases of all diseases, are the least easily recognised, and when cases of cholera occur sporadically, they are doubtless very often mistaken as to their nature, even when they are to a certain extent correctly treated. On the other hand, severe cases generally present certain symptoms in combination, which leave little difficulty in determining their character. The symptoms to which I refer, are vomiting, serous purging, cramps, prostration, coldness, collapse, and suppression of urine. I have, however, seen every one of these symptoms concurrently present in the same patient upon three different occasions, the disease being decidedly not cholera, and probably being fungus of the stomach, similar in character to the uterine disease known by the name of cauliflower excrescence. The gentleman to whom I refer, is subject to severe attacks of pain in the stomach. Some days ago, after much agony, at last alleviated by the external use of belladonna, he vomited several quarts of fluid greatly resembling dirty water, after which he nearly fainted, became extremely prostrate, and then suffered great pain from cramps in the legs. By the application of warmth externally and of turpentine fomentations to the extremities, the alarming coldness of the body was removed within an hour: and he then passed twelve hours without any fresh symptoms to excite alarm. He then, however, became faint, cold, and nearly blind. In these circumstances I was summoned. I had left him an hour previously tolerably well; I now found him collected but deadly cold; the countenance was haggard, and he complained of almost total loss of vision, painful cramps, and utter prostration. After some hours of anxious treatment, in which the external application of warmth and stimulants, along with the internal use of sulphuric acid, were the predominating features, his almost suspended animation returned. He collapse now described was not ushered in by vomiting or purging; but some hours after reaction had been established, he discharged from the stomach by vomiting several quarts of a fluid, resembling cream in consistence and tar in colour. This was undoubtedly blood which had been poured into the stomach immediately antecedent to the time of his rapidly becoming affected with the symptoms simulating the cold stage of cholera.

In this instance (without a previous knowledge of the

history of the case) its character might, and, indeed, must have been mistaken. This case strongly impressed me with the truth of the opinion which is generally, though not universally held, that the collapse and spasm of cholera are not usually, if ever, the direct effects of a morbid poison, but simply the consequences of the serous hæmorrhage resulting from the action of a morbid poison.

A few days before the occurrence above described, my friend Mr. B. W. Richardson had under his care a man who suffered in a very similar way, though the case was not one so liable to be misunderstood. The following notes were given to me by Mr. Richardson.

S., aged 65, was seized, while out of doors, on the 27th of October, 1853, with pain in the stomach, followed by the vomiting of a large quantity of dark coloured blood mixed with clots. He went home and kept quiet; but on the following morning immediately after breakfast, the vomiting having returned with increased violence, he came to Mr. Richardson. He was very cold and faint, his pupils were dilated, his face was pinched, and his voice was weak. There was likewise at intervals involuntary jerking of the limbs. He was ordered to go and keep himself warm in bed, and to take every six hours ten minims of aromatic sulphuric acid in an ounce of the decoction of cinchona. He continued under this treatment for three days, without any return of the symptoms; and he is now perfectly restored.

The collapse of cholera may be closely imitated by the secondary consequence of the serous purging, induced by elaterium and other drugs in inordinate doses.

I have seen scarlet fever patients become collapsed, and die rapidly from sudden and profuse serous purging. Death in typhoid fever likewise occasionally happens in the same way, and I am not sure that in such cases the diagnosis can be made, except from determining the presence or absence of the eruption. In enteritis there is often a series of symptoms similar to those of cholera.

From the preceding remarks, it is very evident that other causes than the cholera poison may induce collapse and spasms, similar to those which characterise the cold stage of cholera. The differential diagnosis has, in fact, repeatedly been a matter of difficulty, both with the medical jurist and with the practical physician. The way to avoid error is to investigate thoroughly every circumstance, and to bear in mind that different causes may, and often do, produce similar symptoms.

III. OBSERVATIONS MADE BY THE AUTHOR DURING PART OF THE EPIDEMIC OF 1848-49.

Before proceeding to speak of cases of disease, it may be well to give a short account of the localities within which they occurred.

The field of observation embraced the suburban parish of Putney, part of which is close to the Surrey bank of the Thames, and contains some insalubrious localities, although, speaking generally, it is a remarkably healthy district. Towards the close of 1848, I was one of a committee of parishioners to whom was intrusted the domiciliary visitation of the whole parish. The following is a verbatim copy of the report given in to the Local Board of Health by the sub-committee which visited that part of the parish described as "the Lower Richmond Road, commencing at Windsor Place, taking in Putney Lower Common, right and left, to the extremity of the parish, where it joins the parish of Barnes". Some parts of Putney Lower Common are close to and almost level with the river Thames.

REPORT, etc. "We have visited every house in this district, and have to report that we find the whole in a very healthy state. But, although we have pleasure to state so much generally, we feel bound to express our surprise that that part of our district on the Common, to the right of the Lower Richmond Road, should be so, for we find the cottages there, or most of them, overcrowded with inmates; some with little or no furniture in them, and from five to seven persons being in two rooms. Dirty, badly clothed, shoeless, and miserably poor boys and girls sleep together of greater age than is

prudent. There are many children running about the Common. In many cases the mothers and fathers were out at work, and the children left in the care of the eldest girl, perhaps about ten years old, without education. No clergyman visits the neighbourhood, nor any members of the Putney Visiting Society. The premises are in a bad state of repair, and the poor persons are much exposed. There is one open privy assigned to ten houses, of which all the tenants complain. A general sink is in the centre of these houses, which occasionally gets stopped up, and then the water lies on the surface, opposite, and near to the doors of the houses.

"These ten form a kind of square. To these, and fourteen other houses, in all twenty-four, there is a good well; but it is open and exposed, and is dangerous among children; and in this small locality we think there are more children than in any other place of its size within our recollection.

"In this place some privies are good, and others bad. The same remark applies to the drains. Some tenants have no drainage, and the wash water is thrown from the houses upon the common. The whole of this property is so situate as to be capable of drainage at little expense. As the parish holds houses here, we recommend this to be done, and that the owners of the adjoining property be required to join in the expense of making an improvement generally, so as to make the spot more conducive to health than it now is. There is a dung-heap here, which must be removed; for, independently of the quantity of dung, the heap tends to stop the soil of a privy from taking its proper drainage course: this drain or ditch requires cleansing.

"There are a few swine in the neighbourhood, but we find no accumulation of dung, nor any annoyance arising from pigs, except in the case of a Mr. P., after mentioned, whose privy and pigsty are in too confined a spot, and too close to several small tenements, to be wholesome.

"The above remarks apply specifically to the spot before named: and as the other parts of our district are not particularly observed upon, it must be understood that we have not anything to report regarding them.

"The owners of the above property are the Parish, Mr. F., Mr. S., and Mr. W.; and the objectionable parts (in connexion with the number of inmates more particularly) are these.

"PARISH PROPERTY. Tenant G., seven persons in two rooms, seven feet high. Privy in bad condition: no drain.

"Tenant J. S., seven persons, five children, none at school. Eldest son twenty; girls ten to seven. Girls sleep with mother and father. Two chairs and one table. Boys sleep on floor. Room dilapidated. Privy bad. Children healthy: good drain.

"Tenant J. R., wife and three children. Boy nearly fifteen. Girls ten and thirteen. Girls and boy sleep together. Privy wants emptying. The house is otherwise very clean.

"Tenant W., wife and five children: two rooms: place in good order: but the tenant should acknowledge a tenancy. It appears the land belongs to the Parish, but the tenant built the house, etc., by permission.

"Tenant T. E. Very clean and good.

"Tenant Mrs. M. She and her son live together in one room. She is eighty-three, and he forty-four. Drains right, but privy wants emptying, and she cannot afford to do it. [N.B. This tenement is not with the others, but is situate to the left of the Lower Richmond Road, opposite Langshaw Lodge, and is merely spoken of here to keep the Parish property under one head.]

"MR. F.'S PROPERTY. It consists of ten houses in a kind of square: in the centre are two sinks, and at the end in a corner one open privy.

"Tenant M., wife and four children. Three rooms.

"Tenant L., wife and five children. Three rooms.

"Tenant R., wife and six children under eleven. Three rooms.

"Tenant H., wife and two young children.

"Tenant W., wife and five children. Eldest son sixteen. Eldest girl fourteen. All sleep in one room, but in two beds. The man out of work, and a most miserable family.

"Tenant S., wife and ten children; but six only at home, from eleven to seven years. Two rooms and three beds, all sleep up stairs. Caroline, eleven years, sleeps alone: five boys together: and husband and wife together.

"Tenant W. and wife. Three rooms. Roof bad, and wet comes in. Woman in delicate health.

"Tenant Mrs. C., and four inmates: three adults and two infants.

"Tenant W. S., wife and five children. Eldest boy at home is eighteen, and eldest girl thirteen: only two rooms. Mother and father, and a little boy of three years sleep together in one bed, and in another bed in the same room the other three boys and girl sleep.

"Tenant C., seven inmates. They use the general privy. No drain; no sink; they throw the waste water before the door on the common.

"MR. S.'S PROPERTY. Tenant P., wife and two children. Plenty of room and underlets. The privy is badly constructed, as also the pigsty. There is one pig in it. The sty is covered in, but too close to three or four tenements; and all the inmates complain.

"This person's dung-heap is away from the premises, but close to Mr. S.'s other property, near L.'s, after mentioned, the soil of whose privy is stopped by it. It should be removed, and the drain or ditch dug out, then there would be a fall, and all would go off clear. This person (P.) is a night-man, and has been known to deposit night-soil here, and some few months ago was made to remove it. Such acts as these should be narrowly watched.

"Tenant B., wife and child. These have all requisite conveniences, with a privy for this and the next named house; but premises are too close and offensive to this and the other tenants close by.

"Tenant T. and son. The preceding remarks apply here. The houses join.

"Tenant L., and wife only. No sink: no sewer: wash water thrown on common. There is a privy conveniently placed at the end of the garden with a fall; but P.'s dung-heap before named, prevents the soil from being carried off. This house does not adjoin the foregoing houses.

"MR. W.'S PROPERTY. Tenant K., wife and child. Tenant R., wife and two children. Tenant D., wife and a little boy.

"The above occupy three tenements in a line with L.'s. They are in want of a drain to connect it with a ditch behind at the end of garden which is well situated. Their privies are at the end of the garden, well away from the houses, overhanging the ditch, which requires digging out; and then, when P.'s dung-heap is removed, the soil would go away in all probability. All complained of P.'s dung-heap, which makes their privies less comfortable.

"There are other houses in this locality not belonging to the foregoing owners. They need not be remarked upon, except

"Tenant J. R., wife and four children. Three rooms. Privy requires attention. They complain of it because their overflow is caused by P.'s privy being badly constructed and out of order. They back each other.

"Tenant B., wife and five children. The privy is in too confined a place, requiring more air. It leads out of B.'s workshop. He is a carpenter. It smells, and must be bad for him who is necessarily confined in it for hours together.

"G., a gardener. He should remove his dung and decayed vegetable matter to another part of his premises, and he has much space. His heap is offensive and unwholesome to Mrs. T. and Mrs. C., behind whose premises it is.

"Wm. S. Privy and drain connected with it were bad. He is clearing them out. There is another drain farther off which should be connected with the preceding. The tenant justly complains of it.

"Mr. H. and Mrs. W. Mr. C. owner or mortgagee. These houses run in a line with Mr. S.'s. There requires a drain to be made here. The houses must be very unwholesome. There is a considerable quantity of water under the sitting rooms, and we learn it remains. It wants to be let off. There is a drain close by, with which it can be easily connected. It would seem as if these rooms were built over a

ditch or fall of water from adjoining grounds. It may be a spring.

"Tenant G. Owner M. In two rooms on the ground floor, he, his wife, and five children live. All sleep in one room. They seem miserably poor. The husband and wife were out at work. He is a gardener with M. It seems a damp place in the winter, but is very open, and we saw no nuisance, but extreme poverty." [Then follow the signatures.]

The village of Putney was, at the period referred to, and still is, extremely ill drained. Nevertheless, from the comfortable circumstances in which most of the inhabitants are placed, and the general absence of excessive crowding, it is a healthy place; and the description which has just been given of the Lower Common is not applicable to the village, nor to the parish generally. I must state, however, that in 1849, there were some houses even in the best parts of Putney which formed notable exceptions; among which I must include my own residence, the drainage of which had never, up to that period, been performed, except by a series of cesspools. In my house, two cases of cholera occurred; and although both recovered, one got well after all hope had been abandoned. Putney Heath and the adjoining neighbourhood are famous for free and bracing air; and, lying far above the range of the river vapours, ought to present circumstances the most favourable for health. At the period, however, to which I refer, ancient unemptied cesspools were in close contiguity with the mansions of the affluent; and in some instances these dangerous depots of filth still remain, saturating the surrounding soil with their exudations.

The suburban village of Fulham, on the Middlesex bank of the river, and only separated from Putney by a bridge, is even worse drained than Putney; and, at the northern extremity of the village, on most days of the year, the air is charged with a heavy stink. I have heard it said that there is nothing unwholesome in this smell; but I cannot help thinking that the causes which generate it likewise give rise to unwholesome emanations. Around the episcopal palace there is a moat or great tidal ditch, which, in its circuit, comes up pretty close to the houses in the western side of the High Street, and to the cottages in the road leading to the Fulham fields. This moat has existed for about six hundred years; and, unless the commissioners of sewers attack it as a dangerous nuisance, it is likely to remain for six hundred years longer; for there is no one sufficiently interested in filling it up. In fact, it is by occasionally discharging its contents through the Fulham sewers, that the imperfect drainage of the village is accomplished.

The subsoil of Putney Lower Common and of Fulham is a stiff clay; but a great part of the village of Putney and of Putney Heath is situated on gravel, through which a large fall of rain rapidly disappears.

All the patients referred to in the following notes were in comfortable circumstances; and, though some of them were in a humble rank of life, they had the full benefit of efficient domestic attendance. From this circumstance, combined with the early period of the disease at which I was sent for, the cases afforded great facilities for studying its natural history, and for successfully applying remedies.

Having now sufficiently glanced at the characteristics of the locality about to be referred to, it becomes necessary to describe the cases of disease which were under treatment during the period specified. We cannot place truthfully on record the constitution of an epidemic, by simply detailing characteristic cases; it is necessary to bring into some degree of prominence every description of disease which has come under notice during the period to which our history refers. By doing this carefully and faithfully, and by such means only, can we correctly communicate to others the facts which we have observed, and upon which our generalisations are founded. Our descriptions, it is true, may in the estimation of some be redundant and overloaded; yet, in epidemiological inquiries, it is safer to be prolix than meagre; in the one case, the reader is able to judge for himself; but in the

other, he is either unfairly entrapped into conclusions, or is prevented from fully testing their soundness by the light of his own reason.

These considerations induce me to mention, categorically, three groups of cases which particularly arrested my attention during the epidemic of 1848-49, all of which distinctly partook more or less of the prevailing epidemic influence.

The following is a summary description of the three groups of cases now referred to :—

FIRST GROUP. *Quotidian fever*, or *febricula*, with diarrhoea, which was not at first serous; hepatic, splenic, and gastro-enteric symptoms being in some cases prominent and in others absent. Cases of this group may be called *epidemic diarrhoea*.

SECOND GROUP. Similar to the first group excepting that the purging was always serous and the type was either remittent or irregularly intermittent. The secretion of urine was scanty or absent. Cases of this group may be called *cholérine*.

THIRD GROUP. The severer cases of the second group passed by insensible gradations into the third; the distinction between the aggravated cases of the one and the milder cases of the other being purely arbitrary and one of degree. The cold stage was sudden and protracted, and passed into collapse. This we term *cholera*.

In the above division, discharge from the bowels is made the basis of classification; or, at least, one of its essential features. This, however, without explanation, might mislead; and I therefore subjoin a more detailed method of grouping, which enables me to embrace every case of acute disease which came under my care within the period embraced, excepting a case of menorrhagia. Of neuralgia, in a variety of forms, I had numerous cases; but the predominating forms were *ague* and *neuralgia of the feet*. Of the latter, I saw three cases in September 1849; and I have had only one since that period. I felt it quite impossible to resist the conclusion, that every case of disease then prevailing manifested more or less the characters of periodicity, associated with neuralgic or choleraic symptoms. At the commencement and close of the cholera epidemic, neuralgia was common; but when the epidemic was at its height, cholérine and cholera seemed to swallow up all other forms of disease.

To present clearly my meaning then, I would say that during the height of the epidemic, the choleraic type was impressed on all diseases, or that there was nothing to be seen except choleraic disease; whereas, at the advent and subsidence of the epidemic, the neuralgic type was distinctly visible, and became gradually displaced by serous diarrhoea, and at last by algide cholera.

During the late epidemic, I recorded the following well-marked

GROUPS OF CASES :—

1. Quotidian fever and quotidian neuralgia; and diarrhoea a subordinate symptom.
2. Quotidian, tertian, and irregular neuralgia—no diarrhoea.
3. Quotidian fever, with gastro-enteric and hepatic symptoms—diarrhoea?
4. Dysentery.
5. Remittent and intermittent serous diarrhoea (cholérine), cramps, and prostration.
6. Cholera in the first degree.
7. Cholera in the second degree; the algide stage being complete.

I feel quite satisfied in my own mind that there is nothing fanciful or overstrained in this grouping of cases; though I willingly admit that in several instances it was only by dint of minute investigation that I could obtain evidence of the occurrence of intermissions and remissions at regular periods. If a few cases be well observed, the truth of my statements may often be corroborated in the future: but of course by those who have hundreds and thousands of cases to deal with, no correct data can be

established regarding the affinities and course of such a pestilence as cholera.

I subjoin some choleraic cases which were observed with great care, and reported many times daily at the time of their occurrence.

CASE I. Mrs. P., aged 30, residing at Holcrofts, Fulham. On the night between August 31st and September 1st, 1849, she was seized with diarrhoea and cramps in the legs, for which she took repeated doses of a mixture which I had prescribed for general use in the family in which she resided, to be used in such emergencies. She felt so much better on the 1st, that she did not think it necessary to have medical advice. On the 2nd, she continued to improve, and considered herself nearly quite well when she went to bed. On both of these days, she had sudden cold fits. About six o'clock in the morning of the 3rd, the characteristic symptoms of cholera set in with great impetuosity and suddenness. She remained in bed some time, unable to make known her condition. I was called to see her at 8 A.M., and found her vomiting and purging incessantly, and pulseless. She had a senile, haggard expression of countenance. The legs were quite cold, as were likewise the arms, face, and abdomen: the thorax was the only part of the body approaching to the natural temperature. The lips and tongue were also cold; and the lips were livid, as was likewise the countenance generally. The intellect was quite clear; she answered questions with great precision, though she articulated with some difficulty, and spoke in a feeble and sepulchral tone of voice. She had cramps in the calves of the legs, but in no other part of the body. There was an uneasy feeling at the præcordia, with a good deal of pain in the lower part of the bowels. She complained of excessive thirst. During the two hours which elapsed before I saw her, the quantity of fluid discharged by vomiting and stool was quite enormous. The discharge per anum had no fæculent odour, and entirely consisted of a fluid resembling the washings of raw meat. There were a very few shreds resembling flocculi of mucus seen floating in it. What she vomited was paler in colour, and was quite homogeneous: it a good deal resembled slightly dirty water. She stated that she had not passed any urine for twenty-four hours, but might have passed some with the stools. A grain of solid opium was administered in the form of pill; sinapisms were applied to the calves of the legs; and the lower two-thirds of the body were enveloped in a blanket, wrung out of very hot water. She was cautiously kept in the horizontal position; and dry heat was applied to the upper part of the body, to avoid the fatigue which would have been inseparable from removing her chemise. Two ounces of brandy were at the same time administered. In ten minutes from the commencement of this treatment, the pulse returned, and gradually increased. She was ordered to take a teaspoonful of the following mixture every hour:

R Tincturæ catechu ʒij.
 „ opii ʒij.
 „ cardamomi co. ʒj.
 Mist. camphoræ chlorof. ʒss.*
 „ acaciæ ad ʒijj. M.

At a quarter to eleven, Dr. James Bird saw her with me; and the following was her condition at that time. Considerable præcordial tenderness, extending to the umbilicus, and along the course of the colon. Respirations 40 in a minute; pulse 100, feeble, and labouring; considerable tenderness at the nape of the neck, accompanied with oppressed respiration and severe headache. The warmth of the body was maintained with great difficulty, by means of sinapisms and bottles of hot water. The mixture was continued; and a liniment of turpentine and pyroligneous spirit was ordered to be applied to the epigastrium and abdomen, until free redness was produced: also to the nape of

* The following is the formula for preparing the camphor-chloroform mixture, according to Messrs. T. and H. Smith of Edinburgh.

R. Chloroform, ʒi.
 Camphoræ ʒijj. M.

The camphor is perfectly dissolved; but, in consequence of the volatility of the chloroform, it is advisable to add another drachm of this fluid.

the neck, and along the spine. She was allowed to drink plentifully of soda-water, to each bottle of which two teaspoonfuls of gin were at first added, but afterwards omitted, as the heat of surface increased.

2 P.M. There had been some slight return of the vomiting, and four stools of the same character as in the morning. There was less abdominal tenderness, and tolerable heat of surface.

3 P.M. There was more warmth in the skin: and the body was bathed in a profuse perspiration. During my visit, there was some vomiting, and a copious discharge from the bowels, similar to that previously described. The interval between the doses of the camphor-chloroform mixture was increased to two and a half hours.

8 P.M. The condition (now and at half-past five) was very similar to that at three o'clock: there had been several stools, and some vomiting. The last motion contained more flocculi than had hitherto been observed; in other respects, it possessed the same characters. The abdominal pain, which was somewhat relieved by the liniment, having returned, it was re-applied. She took the two following pills immediately:

R Quinæ disulph. gr. vj.
Calomelanos gr. iij.
Opil gr. ss. Ft. pilul. ij.

Half of the following injection was administered directly, and the rest was ordered to be repeated in two hours, if required:

R Plumbi acetatis 3i.
Tinctur. opii 3iss.
Decoct. oryze 3viii. M.

4th, 9 A.M. She passed a tolerable night. The other half of the enema was not administered, as there had been no stool. There had been no urine passed. She had been in a profuse perspiration since last report; and, indeed, since between 2 and 3 P.M. yesterday. She had occasional sudden and very transient attacks of nausea, and these were generally accompanied with a temporary augmentation of the perspiration, which was then seen to stream down her face in greater abundance. The tongue was clammy and furred, except at the point, where it is dry and red. The pulse was 100, and the respirations 30 in a minute. She had finished the camphor-chloroform mixture prescribed at the first visit. There was great prostration, which had been relieved by each dose of this mixture.

2 P.M. About 11 A.M. she became much flushed, and complained of intense headache, with pain in the muscles of the back of the neck, and some flying pains of the limbs. The state of perspiration continued unabated. Pulse 130; breathing a good deal oppressed. At half-past one P.M., she passed between one and two ounces of very high coloured urine.

R Quinæ disulph. gr. iii.
Calomelanos gr. vj. M. pil. ij.

One immediately; the other in two hours, if the bowels have not been moved.

6 P.M. She had taken both the pills; but had had no stool. She had, however, passed fully a pint and a half of urine, which, though dark in colour, was not so much so as that mentioned in the last report. On examination, it was found to be acid, of sp. gr. 1022.5: it lost much of its dark colour on the application of heat, and became momentarily clearer; when there were seen, as the heat was continued, milk coloured filaments in abundance. The addition of nitric acid did not seem to produce any change; but, on boiling it with liquor potassæ, there seemed to be an aggregation of the filamentous or flocculent particles into larger bodies, with a clearer appearance of the urine.

According to the report of the nurse and of the patient herself, a marked improvement speedily followed the discharge of urine. She felt much better, and drank a tumbler of cold beef-tea, being her first application for that beverage during the day. She had drunk a large quantity of soda water. Her thirst was now much abated. It is necessary to note, that during yesterday and the night, and this forenoon, she drank many quarts of water and soda water. At

present, the perspiration continued; and was reported to be more abundant than during the height of the febrile paroxysm some hours ago. There was still a good deal of headache; pulse 90, respirations 26 or 28; but the pulse and respiration varied considerably from slight causes, as when she moved in bed, or attempted to raise herself on her pillow.

10 P.M. There was decided improvement in all respects, though she became very faint when her chemise was being shifted. At about 9 P.M., she had a scanty black, fluid, and somewhat fæculent motion. There had been no more urine passed. On sitting up in bed to take a little arrowroot with wine, she was seized with faintness, and had some vomiting.

To be taken immediately.

R Liquor. quinæ amorph. ℥xv.
Ferri sulphat. gr. 4.
Aque 3iss.

To be taken in the morning.

5th. She passed a good night: the medicine was taken as directed, and she had a few spoonfuls of thin arrowroot with wine at intervals during the day. In the morning early, she was described to have awoke pretty cool and comfortable; but between six and seven she became flushed, and had a good deal of headache up to noon. When I saw her at eleven, the pulse was above 100, and the breathing laboured; she was also restless and uncomfortable, but this state did not long continue. She had a black, tarlike, copious stool in the afternoon; after which there was some temporary exhaustion, speedily relieved by a little wine. The quantity of urine passed was excessive; it had now a pale straw colour. Pulse, at eight in the evening, 54; perspiration continued. A good deal of lachrymation was present.

R Calomelanos gr. vj.
Quinæ disulphat. gr. xii.
Pulv. opil gr. iii.
Camphoræ gr. iv.
Ext. anthem. q.s. ut fiant pil. vi.

One of these was taken at 4 P.M., and another at 8 P.M.

6th. At 9 P.M., the four remaining pills had been taken. Towards the afternoon, the perspiration began to moderate, but it never ceased, and still continued excessive. Pulse 78, irregular, small, and compressible. Respirations 32. No stool to-day; but an abundance of urine. She seemed extremely depressed, both in body and mind; and her necessary movements in bed caused much muscular pain. To have a tablespoonful of wine in negus every hour.

7th, 9 A.M. Seven ounces of wine were taken during the night, which was the quantity I had said was not to be exceeded. I found that the last dose had been given two hours before my visit; and that, from the longer interval, she had become cold on the surface, and alarmingly depressed. During the regular continuance of the wine, her condition was represented as more favourable. I directed her to have a tablespoonful of wine every second hour; and on the alternate hours, some veal broth or arrowroot, occasionally substituting the one for the other.

To take one of the following draughts every three hours.

R Spir. æth. sulph. co. 3 ss.
Mist. camph. chlor. ℥ii.
Tinct. cardam. comp. 3 ss.
Mist. acaciæ ad 3i. M.

Mitte tales iij.

Pulse 70, irregular and feeble; respirations 40, catching, and occasionally sighing.

3 P.M. Two of the draughts had been taken, and the wine, arrowroot, and veal broth, given as directed. She was much better; pulse 80, regular, and firmer than in the morning; and surface warm, and bedewed with a gentle perspiration. 3ii. of castor oil to be taken immediately.

Half-past nine P.M. There had been great improvement

since the afternoon, especially since the bowels were moved about two hours ago. The stool was of the consistence of thickish mortar, but not formed; it was of an inky blackness, with some patches of dark green. There had been much less urine passed to day than yesterday, and comparatively little sweating. To take a draught in the morning, similar to those prescribed above; and a pill of citrate of iron and quinine.

The subsequent history of this case it is not necessary to detail. Recovery was gradual. The use of alcoholic stimulants was freely resorted to, and seemed essential to prevent sinking. During convalescence she took—and apparently with great advantage—the citrate of iron and quinine.

CASE II. C. U., aged 2 months, residing in Putney Lower Common, was taken ill on the morning of the 18th August, 1849. She was violently sick, and refused the breast, or food of any kind; and before I saw her at noon, had had a great number of stools. The first towels which had been used, contained some matter like very soft clay-coloured mortar; but the towels in which the latter evacuations had been passed, though soaked therewith, were hardly discoloured in any way. When I was in the house, she passed a large quantity of inodorous, almost colourless fluid from the anus. A mixture of chalk, catechu, and opium was prescribed, and a little brandy in beef-tea was directed to be given *pro re nata*. In the evening, the child was somewhat better. On the following day, she was again worse; but the discharge was again moderated, and for some hours arrested, by means of small doses of acetate of lead and Dover's powder. On the 20th, she seemed improving. On the 21st, about 9 A.M., she had a rapid succession of copious fluid motions, from which time, up to death at 7 A.M. on the 23rd, being a period of forty-six hours, she had no discharge either from the bowels or bladder; and remained in a state of absolute collapse, with the eyes open, and sunken, and the countenance haggard. The alteration in the countenance was described to me as having taken place quite suddenly. By means of the diligent use of hot fomentations, the temperature was maintained at the natural standard throughout the whole of this time; and small doses of beef-tea and brandy were administered every half hour, so long as the power of swallowing remained. Shortly before death, the movements of the hands, arms, and legs, were very active; and this continued long after the surface had become quite blue. I was not present when the infant died; and those who were in attendance could not exactly say the moment at which life ceased; for after they had concluded that death had taken place, notable movements of the arms were observed.

EXAMINATION OF THE BODY, 9 hours after death. *External Appearance.* The countenance was haggard, the eyelids open, and the eyes sunken. The fingers were blue; and there were extensive marks of ecchymosis on the posterior aspect of the trunk, but in no other part of the body. In some degree, the extremely collapsed appearance had disappeared since death; and the fingers were certainly not so blue as during life. There was a total absence of cadaveric rigidity in any part of the body.

Head. The vessels of the pia mater were considerably congested; but not more than is usual in deaths from very many diseases. The brain was of soft consistence. There was no effusion under the arachnoid, or into the ventricles.

Chest. On opening the chest, there was a considerable layer of fat in the integuments. The lungs did not collapse; the left overlapped the heart. They presented a perfectly white appearance. The anterior lobes were oedematous, not in any degree emphysematous; they were bloodless. The middle portion was pallid and oedematous, but not entirely destitute of blood. The posterior lobes were likewise oedematous, and, in their more dependent portions, were almost black from the contained blood: but this coloration seemed to depend more on the character than on the quantity of blood. The posterior aspect of the lung, in contact with the parietes of the chest, was deeply furrowed

by the impressions of the ribs. It may be said of the lungs, therefore, that their prevailing character was oedema; and that, although there was an unequal distribution of blood in them, there was nothing which could be truly called sanguineous congestion.

The auricles and ventricles of the heart contained a very small quantity of black, thickish, but not coagulated blood. There was no fluid in the pericardium, nor any fibrinous clots in the heart.

Abdomen. Here, as over the chest, there was a considerable layer of subcutaneous fat. On displaying the viscera, they were observed to be in their natural position. The stomach and intestines were moderately distended with air, but entirely destitute of solid or fluid contents. A large brown patch was observed on the ascending colon, just above the cæcum. Some portions were reserved for microscopic observation. The spleen seemed to be quite natural, and certainly was not enlarged or congested. The liver was rather more pallid than is usual; its inferior surface had a tarry look. The gall-bladder had a similar appearance, and contained a moderate quantity of tarry somewhat inspissated bile. The kidneys were anæmic. The bladder was contracted, and contained no urine.

The general deficiency of blood throughout all the organs was striking.

CASE III. — Churchill, a labourer, aged about 50, resided in the north-west corner house of Saddler's Buildings, Lower Common. I was summoned at 9 A.M., on the 27th July, a close, sultry morning with an ardent sun, to see this man. His wife, who came for me, said that he had been poorly for two days with aguish feelings and undue purging; that he had taken some mixture from a druggist (prescribed for diarrhoea), which had done him some good, she thought, and that morning he had gone to try to labour in a neighbouring market garden, but was obliged to come home. She described him as cold, rigid, and convulsed, and so ill that she did not expect me to arrive to see him in life. I found him with a blue cadaveric countenance; pulseless at the wrists; his heart beat irregularly; and the surface (excepting the chest), was quite cold. He could articulate distinctly, but his voice was weak, and his words were slowly uttered. I had him carried from his chair, stiff and doubled up as he was, and laid in bed. From the severity of the cramps, it was impossible to get him out of his sitting position; the legs and abdominal muscles were rigid, and occasionally violently affected with spasmodic movements. At the moment of my arrival, there was no evacuation going on; but it was stated to me that for an hour previously a fluid resembling dirty water had poured from the bowels. He had likewise had vomiting of a similar fluid. The patient seemed moribund. I had with me pills of camphor and Cayenne pepper; but his efforts at swallowing were not successful, though they were determined and intelligent. A little time was lost in getting some camphor-chloroform solution, which was administered in large doses every ten minutes; but, before he began to take this medicine, hot bags of salt were placed around him, and a large sinapism to the spine. In the course of an hour and a half, during which this treatment was unremittingly continued under my personal superintendence, the pulse became apparent at the wrist, and the body became warmer. The cramps likewise abated; and the blueness of the skin diminished. I then left him in charge of Dr. Henry, who continued the treatment with some modifications. At 2 o'clock, I found him going on favourably, and at 4 P.M., in my presence, he swallowed a cup of cold beef tea. At 7 o'clock, he was very hot, and complained of acute pains in his limbs and of headache; he seemed drowsy, which was not surprising, as he must have taken, within twelve hours, more than a scruple of camphor. All medicine was now suspended; but the warmth was ordered to be kept up, and the friction continued at intervals. If thirsty, he was to have draughts of water acidulated with sulphuric acid, and some cold beef tea at specified periods.

I did not see him for eleven hours. He had passed

the night uncomfortably; but there had been no return of the coldness, collapse, or purging. No one could have supposed that it was the same man, so entirely had the features changed for the better. There was a great moisture on the skin; and the kidneys, which had on the previous day secreted no urine at all, were now rather active. He complained of an uneasy and distended condition of the bowels, for which I prescribed a full dose of castor oil with some laudanum and carminatives. Towards evening, he had a stool without much feculent odour; and, about an hour afterwards, he had simultaneously slight rigors, with a discharge of serum from the bowels. He then had a draught of camphor, chloroform, and creasote.

Next morning, the report was favourable; and he was certainly better. I then prescribed, to be taken three times daily, disulphate of quinine with sulphuric acid; each dose containing four grains of the disulphate, and fifteen drops of the acid. This treatment was continued for two days: when he was able to walk out. After that time, he continued to take the medicine for several days.

CASE IV. Mrs. C., wife of the preceding, had a severe attack of serous purging, with subsequent coldness of the surface on the 28th of July. I saw her two hours after the first liquid stool. She never had another serous evacuation from the time that she took the first dose of a mixture of creasote and mucilage. Each dose contained three drops of creasote, and she took three doses in as many hours. Next morning she was very weak, and the tongue was furred. She took a dose of calomel and rhubarb, and for several days afterwards, though apparently perfectly recovered except as regarded her strength, she took citrate of iron and quinine.

CASE V. Loveday, a labourer. The symptoms and the treatment very similar to those of Mrs. C. For sixteen hours he passed no urine. I mention the case because it also occurred on the Lower Common, and in a house close to that occupied by Churchill and his wife, and on the same day in which Mrs. C. was seized.

At the same time I was attending upon the Lower Common (along with the above cases) four cases of diarrhoea in one family, two cases of severe neuralgia, and a case of fever (Thornton), with the remittent type so obscurely marked as perhaps to bring it under the designation of continued fever. There was no purging or collapse in these cases. An infant in an adjoining house was also at the same time under my care, with the usual symptoms of infantile remittent fever. Other cases of disease were under treatment in this locality by other medical men at the same time; but some weeks afterwards, upon diligent inquiry, I found that there was no sickness. The susceptible population had probably been exhausted by the outbreak, which occurred about the 27th and 28th of July.

CASE VI. J. R. B. C., my son, aged 13 months, was seized on the morning of the 10th September, 1849, with serous purging. This was restrained by chalk and Dover's powders, but not until extreme exhaustion had occurred. The temperature of the body was maintained by the application of external warmth. A stimulating liniment was rubbed in over the spine, and I administered thirty drops of brandy at very short intervals, according to the demands of the languishing circulation. The pulse and the respirations were very slow; but towards evening they both increased; and the external warmth and the brandy were less called for. About four in the morning of the 11th, he became blue and cold, and the inodorous watery fluid poured from his bowels. An enema of acetate of lead was at once administered. Warmth was diligently applied to the surface, and brandy was again freely administered. By these means, complete collapse was probably prevented. He did not, however, rally so well as on the previous day; and although the body was kept warm by artificial means, the blueness of the skin never disappeared, and the tongue and breath were cold. During this day, very small doses of the citrate of iron and quinine were given every hour.

He drank several pints of cold beef-tea, to the doses of which were occasionally added brandy. Between 5 and 9 P.M., he had a more life-like appearance; but the tongue, which had hitherto been cold and moist, became hot and dry. He perspired slightly from nine to about five or six in the morning, and seemed altogether better than he had done since the first attack. Suddenly, however, the former symptoms recurred—the blueness, the cold surface, and the serous purging. The quantity evacuated was not nearly so large as on either of the previous attacks, which was perhaps attributable to the acetate of lead enema having been administered without a moment's delay, on the first gush from the bowels. He had evidently, however, by this sudden relapse, lost more ground than he had previously gained; and while his mother and I personally continued to keep up artificial heat, and to administer the citrate of iron and quinine, the brandy, and the beef-tea, we had no hope of life being prolonged many hours. We now resolved, that if he showed the slightest disposition to rally, we should be ready at once to start with him for Brighton, to give the chance of benefit from a change to sea-side air. He hardly improved; but still we determined to go; as by remaining, death seemed inevitable on the next recurrence of the previous symptoms.

He was carefully wrapped up in flannel, wadding, etc., and hot water vessels were applied around him; but when about to be carried down stairs, a sudden gush from the bowels, and his shrunken death-like aspect, made me hesitate as to removing him, as it seemed, merely that he might die from home. However, the acetate of lead enema was repeated, and brandy was freely given. Though the tongue was cold, and the body cramped, he swallowed easily, and I might almost say greedily, whatever was put into his mouth. He decidedly improved in warmth and in appearance as we went along; and when we reached Brighton, there could be no question as to his being better than when we left Putney about three hours previously. There was no more serous purging. From the time of his leaving Putney, he had no medicine of any kind for twenty-four hours. The treatment consisted more in watching than in acting. During the night he became very hot, and continued so during the greater part of the next day. He passed no water from the previous evening till the afternoon of the day following his arrival in Brighton; and how long previously the kidneys had ceased to act, I cannot say. He seemed every hour to improve, and in a week was out of danger; though for more than twelve months afterwards he had a puffy skin and an anæmic aspect. When at Brighton, he continued to take the citrate of iron daily, and had occasionally some doses of hydrargyrum cum creta.

In addition to the cases detailed, I had, subsequently to the illness of my child, four cases in Fulham, and nine in Putney, in which there were more or less of the algide stage with cramps, as the sequence of serous purging. The treatment adopted in all of them was external warmth, and creasote internally. In some, acetate of lead enemata were used; and the majority had either ammonia, camphor, or brandy, as a stimulant. All had iron and quinine during convalescence. I never felt any temptation to use calomel or other medicines empirically. Each successive case tended more or less to convince me of the paramount importance of arresting the serous discharge from the bowels, and of diligently maintaining warmth.

In one case (Oatts, Gardener's Lane), at the suggestion of Dr. J. Bird, who saw the case, quinine was freely given from the first in consequence of the distinctly marked ægæ type being present. I was convinced that the quinine did much good.

IV. PATHOLOGY OF CHOLERA, INCLUDING ITS MORBID ANATOMY.

The history of the cholera epidemics of 1832 and 1849 points out a clear course to sanitary reform, and it assuredly holds the torch of truth to the physician, pointing out to him the true pathology of cholera, and the means of that pathology, guiding him to the remedy.

he is to apply the abundance and variety of his therapeutic resources.

The first subject which suggests itself for investigation is the relation which cholera bears to other diseases, which, while they require a general epidemic influence to cause them to be severely felt upon a community, have likewise a necessity for the assistance of endemic or local causes, before this can take place. We have also to consider whether cholera be a new disease.

Marsh miasmata, and the putrid exhalations from decaying animal and vegetable matter, are really the chief causes of intermittent, remittent, and yellow fever; although, most probably, these diseases, or rather, we should say, these modifications of the same disease, may, in their more intense forms, and under certain peculiar circumstances, be communicated by personal contact, and thus show themselves beyond the territorial range of the miasmata. They do not each, however, originate in distinct specific poisons; nor do they originate in morbid animal poisons, like scarlatina and typhus—diseases which are, in the strictest sense of the term, contagious. The true state of the case seems to be this; that miasmatic fevers cannot be propagated to any extent where there are no miasmata prevailing; but that a partial eruption of cases may occur, depending on contagion. The effect produced by a change of wind points out strikingly how fevers are rapidly carried from one place to another. Dr. Dundas, quoting Lancisi, informs us that thirty people being out boating on the Tiber, the wind suddenly veered round to the south; the consequence of which was that twenty-nine out of the thirty were seized with fever. The miasmatic diseases already named, however, while they essentially differ from typhus and scarlatina, do not differ pathologically from each other; the apparent distinctions between their phenomena depending upon accidental causes, such as climate, temperature, and what, for want of any other term, we must, with Sydenham, call the epidemic constitution of the atmosphere.

A very cursory glance at the statistics of malarious fevers in the West Indies will convince any one how much the type of the fever is influenced by the condition of the atmosphere, especially as regards temperature, winds, and electricity. A hurricane has been known to convert the most malignant type of yellow fever into a manageable intermittent. This fact is of itself sufficient to establish the pathological identity of intermittents and remittents, which have been so often described as essentially differing from each other.

The previous sanitary condition of individuals is also a remarkable element in determining the type and gravity of the fever. The degree of exposure to the miasmata, the sudden or gradual nature of that exposure, are circumstances which give a character to groups of cases. Persons going from a healthy district to one where ague is prevailing as an epidemic, are generally seized, not with the *intermittent*, which is affecting the natives and long residents, but with *remittent* fever; *i. e.*, with the same disease in a more aggravated form. When a yellow fever epidemic breaks out, the acclimated and non-acclimated, regarded as two classes, are attacked with diseases of very different degrees of malignity; and, in both, the periodicity of the fever is strikingly modified. For example, it often happens that, when the acclimated are attacked with a common intermittent fever, the non-acclimated are swept away by a more pernicious form of the disease, by remittent fever, or by that more intense form called yellow fever. Europeans, on their arrival in the West Indies, are very commonly seized with bilious remittent or yellow fever, which, from this circumstance, are in their cases properly called "seasoning fevers", or the fevers of new-comers; and, indeed, they may be truly called the fevers of new-comers, for new-comers are seized by them even when there is no prevailing epidemic. Here we have an illustration of endemic causes being sufficient to originate, in one class of individuals, a certain definite train of morbid phenomena, which require, in another class of persons, the operation of epidemic as well as of endemic causes. The pestilential miasmata are,

therefore, we must suppose, floating constantly in the atmosphere of these places, or in the water used by the inhabitants, but not in sufficient abundance, concentration, or virulence, to affect those who have become habituated to their influence, though abundantly potent to give rise to fever in persons suddenly, or for the first time, exposed to them.

It does not seem necessary to prove that cholera is a malarious disease. True though it be, that the pestilence has travelled to our shores from the far East, and that we must therefore recognise, as essential to its propagation, a specific poison or a specific constitution of the atmosphere, yet it is equally true that it has only been able to do its deadly work on a large scale on the banks of rivers, or amid the inhabitants of districts ill drained, or the air and water of which have been notoriously contaminated by open privies, cesspools, or other putrescent nuisances of like character. In a word, the recent vital statistics of the Registrar-General unequivocally corroborate what Macculloch averred in 1828, from the comparison of various data, that cholera is a disorder produced by malaria.*

The apparent exceptions to the malarious character of cholera are not stronger than those which have been brought forward to disprove the malarious origin of ague. For example, in the Alentejo, a province of Portugal, south of the Tagus, 500 feet above the level of the sea, and entirely devoid of marshes, intermittent fever is endemic, and hardly any one escapes. The whole country is covered with Gum Cistus, in rank vegetation; and the surface abounds in rocky debris, wonderfully retentive of moisture. These circumstances abundantly explain the prevalence of miasmatic fevers. With regard to these diseases, it must also be remembered that they may be disseminated to a small extent by personal communication; and still more by corrupt water, as is abundantly proved by facts such as those which Dr. Snow has collected.

It has been the ignorant or interested boast of the bone-crushers of Lambeth, that the emanations from their stores of putridity are harmless, because those living on the premises have been more exempt from the epidemic than others at a little distance. If this be a fact, it is one which admits of a ready explanation. Those resident on the premises are acclimated; whereas those living at some distance have the seeds of pestilence sent to them only fitfully, according as the wind may blow. There can be little doubt that the ravages which cholera has made in Milbank Prison are mainly dependent upon the putrid bone-yards on the opposite side of the river. The prisoners are probably, in the majority of cases, feeble, dissipated characters; they are also suddenly brought into the malarious atmosphere; and these two circumstances, when taken in connexion with the mental depression which we must suppose to exist more or less in every prisoner, point out how it is that they may suffer from the pestilential emanations referred to, while those residing in the midst of them are less frequently or less severely affected. The same remarks will hold good with reference to the horrible graveyards of the metropolis, which have been recently shut up; and to the filthy bilgewater in the holds of vessels, which accounts for the outbreak of cholera in ships at sea. In the autumn of 1843, the modification effected upon the fever prevailing in Edinburgh, by previous residence, was well seen. Tramps, vagrants, and Irish reapers, upon arriving in Edinburgh, were in general seized with the disease in a much more virulent form than those of the same class, and of precisely the same habits, and inhabiting the same localities, who had been resident for some time before their seizure.

Duflot states, in his work on "Yellow Fever", that persons habitually exposed to putrid emanations, as tanners, tallow-chandlers, and soap-boilers, are less liable to that disease than agricultural labourers, who work under an ardent sun, or smiths, bakers, etc., and others, who are subjected to great heat within doors. There would, therefore,

* Macculloch, John, M.D., On Remittent and Intermittent Diseases. London: 1828.

seem to be something preservative in being habituated to the operation of the same poisons which dangerously or fatally affect those suddenly brought into contact with them. Every one can, within his own experience, recall cases in which malignant fevers have suddenly broken out in houses where the sewerage or cesspools have been allowed to contaminate the water-cisterns, or the air of the apartments.

Illustrations might be indefinitely multiplied, to show how much accidental circumstances may modify the type of disease; and, having premised thus much, we become better prepared to appreciate the doctrine of Dr. Billing, Dr. James Bird, Dr. Charles Bell, and others, that cholera is pathologically of the same family as intermittent fever; that it is, in fact, a pernicious ague, as was long ago believed by Alibert, Comparetti, Sydenham, and Morton.

The doctrine which is most in consonance with my reading and observation, is very concisely stated by Dr. Billing in the following sentences. "Under the denomination of ague, I include remittent as well as what are called intermittent fevers. Ague is essentially fever: it forms, however, a connecting link between fevers and neuroses, as a considerable degree of nervous sensibility exists in it. Ague is, besides, closely allied to Asiatic cholera and influenza, which are also essentially febrile diseases, as I demonstrated in 1832, when we had daily opportunities of seeing the epidemic." (Billing's *First Principles of Med.*, p. 236.)

Various methods may be suggested, by which each may examine for himself the question as to the resemblance between, or rather identity of, cholera and ague. For example, we may examine the records of various epidemics of intermittent and remittent fever, wherein we shall find abundance of cases which might truly be designated cholera. I have now before me the work of Alibert, entitled *Traité des Fièvres Pernicieuses Intermittentes*, originally published fifty years ago. This author hesitates as to whether *cholera-morbus* ought to be considered as a distinct disease, or as a variety of pernicious intermittent fever.* He quotes the following illustrative case from Torti:

"A man, aged 64 years, was attacked by simple tertian fever, accompanied by bilious vomiting, and dejections of the same character. These symptoms had, on several previous occasions, complicated diseases by which the patient had been affected, which induced Torti to administer the remedies reported to have been previously beneficial in similar circumstances. But after the fourth or fifth paroxysm, the phenomena indicated a frightful intensity in the disease; the vomiting was violent and copious, and the stools followed each other almost without an interval; and each time he vomited or was purged, there was extreme anxiety. The symptoms which succeeded were, a general coldness, a feeble pulse, sighing respiration, hiccup, sunken eyes, lying in the supine position, and an almost total inability to perform any muscular movement. In this alarming state of matters, it was probable that deglutition would be very difficult, or that if the patient did swallow anything, it would be immediately rejected. The danger was imminent; the sacrament was administered to the patient; when, although everything seemed to announce speedy death, Torti resolved to give cinchona in large and often repeated doses. The symptoms did not diminish; and, although there were no fresh paroxysms, the condition of the patient remained very critical. The pulse gradually became restored; but the heat was with extreme difficulty re-established. The cinchona was continued for several days in large doses; by the use of wine, which the patient could hardly retain during the first few days, his almost extinguished life was supported. In a few days, he was convalescent, having been (so to speak) recalled from death to life."

Alibert says that the predominating symptom which constitutes the disease (fièvre pernicieuse intermittente hépatique ou atrabilieuse), is a copious and frequent flux from the bowels, resembling the washings of raw meat (semblance

à la lavure de chair); and which was described by the ancients under the name of hepatic flux. "It first shows itself," says he, "without any symptoms of apparent danger; but it speedily induces extreme prostration of the vital forces. The pulse becomes small and feeble; the voice is sharp, and sometimes aphonia comes on. There is a remarkable chilling of the body and of the extremities. The patient has such a tendency to fainting, that it occurs whenever he attempts to get out of bed. The intellectual functions are, nevertheless, unchanged." (p. 15.)

Comparetti, in his work entitled *Risconti Medici della Febbre Larvate Periodice Perniciose*, published at Padua in 1795, speaks of a species of double tertian fever, which he designates *collerica sincopale*, in such a way as to show very clearly the correctness of the views which it is at present attempted to illustrate. The diminution of animal heat, and the weakness of the pulse, characterise the cold stage of the fever, rendering it truly a stage of collapse.* The remedies which he recommends are laudanum and cinchona. He refers to three cases of intermittent fever described by Morton, which had the mask of cholera, and which had alarming symptoms of delirium, violent spasms, and purging. It appears that Raimond-Restaurant treated choleraic intermittent fever by cinchona in 1680. Scanty or suppressed urine forms a leading symptom in the histories of cases of choleraic intermittent fever, described by the authors whose names have been already mentioned.

Dr. Webster, in 1832, satisfactorily showed that cholera with a well marked intermittent type was, in the time of Sydenham and of Morton [1669-1693], a great scourge of London. It was called cholera morbus by these physicians, and, in the Bills of Mortality, "gripings in the guts", and "plague in the guts." In 1669, when the population of London was only 600,000, the deaths from this disease were 4,385.

Enough has now been said to show that cholera is not a new disease, that periodicity has been long ago recognised as an essential character, and likewise that its treatment by antiperiodic remedies is of equal antiquity.

It may, however, be interesting, as corroborating the doctrine that cholera is a form of intermittent fever, to refer to the following extract from the New Statistical Account of Scotland, regarding the medical statistics of Kelso, a town in the county of Roxburgh, during the cholera epidemic of 1832. It is well known that an improved agriculture has extirpated ague from many districts, where it used at one time to prevail. Its total disappearance from the county of Haddington, where it was formerly endemic, must be ascribed to an amelioration of the atmosphere, the result of the drainage of the land, which has there been carried out on a scale of great extent and magnificence. The same cause has produced a similar effect in Kelso, and many other places. The following table is compiled from the records of the Kelso Dispensary.

In 1832, it is said that the increase in the number of agues was apparently occasioned by the opening of some drains in a piece of marshy ground. It was in this year that cholera visited Kelso with such fatality; and, for two months, the dispensary was used as a cholera hospital; during which time, no records of the other cases were kept, so that the cases of intermittent fever for that year must have been more numerous than they appear in the books.†

* "La febbre per l'ordine degli accessi, per la qualità, e relazione di alcuni sintomi, per la remissione de' più gravi in certe ore, per la qualità dell'urina, pel difetto del calore, per la debolezza del polso, e pel cambiamento di tali caratteri nell'uso del febrifugo dichiarasi periodica del genere delle doppie terzane, e della specie perniciosa collerica-sincopale."—Comparetti, part. II, p. 414.

† The table quoted in the text possesses considerable interest in several points of view. It appears that the years 1780, 1781, and 1782, were very severe upon the lower orders, in consequence of the inclemency of the weather, and the scarcity of food. In addition to the heavy list of fever and ague cases, there occurred, during that period, twenty-one of scurvy. In 1781-82, there was an unusual number of cases of dropsy, depending, there can be little doubt, upon the great prevalence of intermittent fever during the preceding years. Asthma is often a sequel of intermittent fever; and by reference to the table, we see this well illustrated. Probably, the asthma, which follows intermittent and remittent fevers, and likewise cholera, is the result of the peripheral portions of the lungs never recovering from the capillary congestion characteristic of the primary diseases.

* "Si l'on a égard au cholera-morbus, considéré comme indépendant de la fièvre pernicieuse intermittente, aucune affection peut-être n'a été décrite avec des couleurs plus vraies, plus énergiques, dans les épidémies d'Hippocrate."—Alibert, 4ème édition. Paris, 1806, p. 14.

The effect of malaria is to render the blood dark coloured, and to cause a breaking up of its globules, and consequently the imperfect elimination or a complete suppression of the normal secretions. Majendie has produced artificially, in dogs, these effects by injecting a small quantity of putrid water into a vein. In reference to the appearances found on dissection, he says: "Among the pathological phenomena presented by animals into whose veins putrid water has been injected, we have principally remarked among the intestines that which is commonly called acute inflammation, or in other words, an exhalation of a matter of the colour of the water in which meat has been washed, as pathologists have so happily described it. This matter, adherent to the mucous coat of the intestine, and solidified in the form of jelly, is, in reality, a portion of the fibrin of the blood, which has transuded and become coagulated in a peculiar manner in the cavity of the digestive canal. Here is the way in which we prove this position. We have detached and washed with care this intestinal secretion, we have removed the colouring matter from it, and it has precipitated very minute particles of fibrin. I intentionally make use of the word particle, for it is in some respects different from a globule; the latter being to a certain extent organised, and affecting a determinate form, and because globules constantly present a great analogy the one with the other, whereas, on the contrary, what I term particles, are merely a heap of extremely delicate parcels, differing in form and volume, and to which one cannot attach any idea of regular or symmetrical configuration."* These masses, since they do not possess the cellular structure of coagulated fibrin, or of accidental tissues, cannot be regarded as the results of inflammation; and it is probable that, were the analogous masses found in the intestines in cholera and yellow fever to be similarly examined, they would present the same physical characters.

The condition of the blood and of the internal organs in persons who have died of cholera has been made the subject of laborious investigation by Garrod, Gairdner, Raikem, Levy, and other pathologists. It is to be regretted, however, that, in many of these observations, sufficient attention has not been paid to the stage of the disease in which the patients have died, and especially to the amount of serous draining which has taken place; for it is evident that on this must in a great measure depend the state in which we shall find the residual blood.

In his valuable paper on the "Blood in Cholera", published in the *London Journal of Medicine* for May 1849, Dr. A. B. Garrod draws the following conclusions from his own investigations, and from those of Drs. O'Shaughnessy, Thomson, and Clanny, and MM. Lecanu, Rose, and Wittstock:—

"1. In cholera, the physical characters of the blood are altered, and its tendency is to become thicker, tar-like, and less coagulable.

"2. The proportion of water is much diminished.

"3. The specific gravity of the serum is very high, which is due to the increase of the solid portion of the serum, and especially of the albumen; and the fluid also tends to become less alkaline in its reaction.

"4. The saline constituents of the blood are not only not decreased in amount, but sometimes exist even in increased proportion; and the diminution of its alkaline reaction is not due to the loss of salts, but to the impeded excretion of organic acids which are constantly being formed in the system.

"5. Urea usually exists in increased quantities in cholera blood, but the amount differs considerably in the different stages of the disease, being but small in quantity in the intense stage of collapse, increasing during reaction, and in excess when consecutive febrile symptoms occur."

Dr. W. T. Gairdner, in his "Memoir on the Pathological Anatomy of Cholera", published in the *Monthly Journal* in 1849, says: "The remarkable viscosity so often noticed was chiefly observed in cases fatal during the collapse or early reaction; and was certainly owing to the removal of the fluid matter by the intestines." These remarks of Dr. Gairdner I believe to be very correct. It is to the excessive evacuation of the fluid part of the blood that we must refer the spissitude of that portion which remains in the vessels: and it is from the examination of patients dying in the stage of collapse, or of early or feeble reaction, that the description of the blood in cholera has mainly been taken. Of the blood in the earlier stages, less is known; but Dr. James Bird, after stating that he was rarely able to obtain blood from the veins of patients in the collapse, says that, "in the earlier periods, the blood flowed more freely from the veins of the arm, though it trickled down in a small feeble stream"—evidently showing that, although alteration had commenced, it had not become so far inspissated as is commonly described.

Dr. Zarlengo of Naples, says that cholera is a disease in which the blood is unfit to support life. He remarks—*"Hæc crasi corrupta fit ut sanguinis serosa pars e cruore disjunctatur ac ad tubum gastricum congregatur; ex quo evenit, ut materia serosa continuo vomatur aut per alvum ejiciatur, dummodo membrana serosa atque vesica urinaria, liquore omnino carens, exarescit."* (Quoted by Knox, *op. cit.* p. 50.)

The remarks which I have made with regard to the importance of noting the stage of the disease apply with great force to the pathological conditions of the internal organs. Let me take an example from among other diseases. A patient may die in the early stage of scarlatina, and may have had anasarca and albuminuria, but we may find the kidneys only congested; whereas, if we examine these organs in one who has died after suffering from dropsy and albuminuria for weeks or months, we shall probably find degeneration. The observations of Drs. Gairdner and Raikem were made on patients who had died in the stage of collapse; and they, as well as those of MM. Levy and Tholozan and others, point to a general deficiency of blood in the system; many organs presenting the appearance of bloodlessness in a marked degree. It is true, that "congestion" and "sanguineous infiltration" have been mentioned by MM. Levy and Tholozan, as being found in the algide stage; but these phenomena are by no means to be confounded with the congestion or subacute inflammation arising during reaction. They are, I think, chiefly mechanical effects of the thickening of the blood; and in this way also are to be explained the "subpleural ecchymoses", "hyperæmated vascular ramifications in the gall-bladder", "hyperæmated villosities" in the stomach (Raikem), and the ecchymoses, arborisations, etc., described by Levy and Tholozan as present in the intestinal canal. These observers mention the congestion of the kidneys, and effusions in the lungs; but they also describe the blood procured from these "congested" organs, by section and pressure, as being thick.

I have not considered it necessary to enter minutely into the appearances presented by the various organs in cases of death from cholera, believing that more information is to be gained from a careful consideration of the alterations produced in the blood. It is simply absurd to fix on any part, and to say that, because we there find "congestion" or "inflammation", cholera has its seat there.

* Majendie, *Leçons sur les Phénomènes Physiques de la Vie*, tome iv p. 226. Paris, 1836.

If indeed any of the appearances of hyperæmia found in cholera patients are referrible to the same causes as the eruptions of measles or scarlatina, or to the bronchial or renal congestions in these diseases, they are not, in the present state of our knowledge, to be distinguished from those—probably the most numerous class—which obviously arise from the cause to which I have already so often referred—the inspissation of the blood, and the consequent impediment to its passage through the capillaries.

The adoption of the following conclusions seems to be justified by the facts and analogies now brought under review:

1. Cholera is a fever, intimately related to those fevers which depend on malaria.
2. The intermittent or remittent type can be generally recognised in the milder, and also not unfrequently (though less distinctly) in the severer cases.
3. The stage of collapse ought to be considered as an aggravated cold stage of the paroxysm of a pernicious fever, which may spontaneously terminate in death or reaction.
4. The least dense portion of the blood has an excessive tendency to exude through the capillaries of the stomach and bowels, and pass from the body by vomit and stool.
5. The inspissated residual blood being unable to pass through the small pulmonary vessels, causes congestion of the lungs; and as speedy consequences of this condition, paralysis of the right side of the heart from over-distension, asphyxia, and other subordinate derangements of the vital actions.
6. Death may take place from
 - a. Asphyxia.
 - b. Necræmia, with loss of the least dense portion of the blood by stool and vomit.
 - c. Necræmia without such loss of the least dense portion of blood as can be discovered during life—the exudation remaining within the stomach and intestines.
 - d. Toxæmia from absence or deficiency of sanguineous depuration.
 - e. Inflammation of lungs or other organs supervening in convalescence.
 - f. Debility.
 - g. Gastro-enteritis.
 - h. Two or more of the above causes combined.
7. The anatomical lesions found on dissection vary with the causes of, and circumstances attending, death.

V. TREATMENT OF CHOLERA.

The advocacy, by many, of a uniform and empirical system of treatment of cholera, has greatly tended to obstruct the progress of rational inquiry. Several plans, and particular remedies have been found useful; and practitioners, impressed by the published account of this success, have too often contented themselves with empirically repeating the instructions of others, without carefully analysing the facts and seeking for a rational explanation of the *modus operandi* of the therapeutical agents which they employ. The stage of the disease has not been sufficiently noted in relation to the therapeutic means employed; and recoveries have been too largely designated cures. With one, capsicum has been the specific; with another, camphor; with another, sulphuric acid; with another, acetate of lead; with another, quinine; and so on might the list be indefinitely extended. Now, that all of these and other medicines are *par excellence* cholera remedies, I perfectly believe; and it seems to me that a more successful treatment is to be discovered by a judicious application of the means which we possess, than by searching for some new specific.

It seems to be of primary importance to bear in mind that we have a poison-disease to deal with, resembling, if not indeed identical with a pernicious ague: that it has a course to run, which may be modified and curtailed, but which, even when let alone, shews a disposition to terminate in recovery. We have, therefore, in the first stage, in which chills and

other premonitory symptoms of discomfort may be present, to adopt measures which may be regarded as prophylactic rather than curative. It is in this stage that the pernitrate, or some other preparation of iron, and the disulphate of quinine, are of signal benefit. Here, however, we must not follow a blind empiricism. We must, if the digestive system is at fault, combine with the use of these special medicines a judicious alterative system; and, should there be any tendency to copious watery evacuations,—the serum of the blood,—we must be prompt in our administration of those remedies which are generally termed hæmostatics; among which may be particularly mentioned quinine, sulphuric acid, nitrous acid, acetate of lead, creasote, and nitrate of silver. If the case should proceed a little farther, in spite of our endeavours to arrest its progress, or should the case, from its inherent intensity, or from neglect, not present itself for medical treatment till the secondary effects of the loss of serum have become apparent, we may probably find it useless to think of the quinine, and be obliged to treat the cramps and collapse which threaten speedy dissolution. The necessity for diffusible stimulants is now apparent: and, of them all, as a general rule, camphor will be found the most useful. It can be conveniently administered in large doses by dissolving it in chloroform; and the solution combines so well with creasote, that it will often be found prudent to confine our administration of medicine to frequent doses of a mixture of camphor, chloroform, and creasote. The chloroform is useful as affording facilities in dispensing; and it cannot, in the small quantities administered, do any harm. The camphor acts quickly as a diffusible stimulant; and the creasote has a powerful effect in restraining the serous discharge. Indeed, I am inclined to think that its beneficial effects are not much, if at all inferior in this respect to those of sulphuric and nitrous acids. External warmth, and the use of stimulating embrocations, are very beneficial in conjunction with the internal use of camphor. The suppression of urine is not a symptom which is to be relieved by the administration of diuretics; it is a necessary consequence of the congestive paroxysm of the disease, and its removal is likely to follow the cessation of that paroxysm.

Enormous doses of opium, of calomel, and of other powerful drugs have been given to cholera patients; and there can be no doubt that such substances, when introduced into the system when in a state of collapse, are not likely to produce any very suddenly appalling effects. And indeed, in a vast number of cases, they seem to lie as quietly in the stomach of the cold cholera patient, and to produce as little effect, as if they were deposited in a glass bottle. Should the patient, however, emerge from the state of collapse, he runs as great a risk from the poisonous doses of these medicines which have been placed in his interior, as he has just escaped from the pestilence. Large quantities may certainly pass off by the bowels, unacted upon; but it cannot be questioned that in a very great number of cases which have been treated in the way mentioned, patients have had their convalescence abruptly arrested by fatal narcotism or exhausting salivation. The use of opium and calomel, in ordinary doses, is often necessary: but the inordinate doses of these medicines formerly, and perhaps still, employed by some, cannot be too much condemned.

The importance of arresting the serous discharge, and of maintaining the warmth of the body by the application of heat externally, cannot be over-estimated. In fact, the judicious carrying out of these intentions constitutes the essence of the treatment of cholera. Other therapeutic measures may be regarded as liable to considerable variety, according to circumstances, and as valuable and auxiliary, rather than as always indispensable. The prompt arrest of the serous discharge, by creasote, sulphuric acid, nitrate of silver, or other remedy, has undoubtedly saved innumerable lives; and from amid the chaos of contradiction, depreciation, and laudation, in which the merits of special modes of treating cholera are involved, the diligent application of warmth to the surface can be extricated as a measure of established value.

Mr. Barwell, in a little work just published, says: "It is

a grand essential to keep up the temperature of the patient, since the tendency to become cold is certainly a great characteristic of this disease. Hot bottles should be placed to the feet, and inside of the thighs; and India-rubber bags filled with hot water to the loins and abdomen. The bed-clothes must be ample, and should be so arranged, by means of an extra blanket wrapped round the shoulders, or passing round the chest and under the arms, that he does not bare that part to the cold in his restless jactitations, nor in rising on the elbow to vomit, as he may perhaps frequently be obliged to do." These recommendations of Mr. Barwell are sound and practical. They are, moreover, firmly based upon facts which came under his observation in St. Thomas's Hospital. In the following passage, he states very clearly, and, I think, very correctly, the relative value of internal stimulants and external warmth in cholera; and he also refers to the hospital experience already referred to, upon which his opinions are founded.

"Stimulants," says Mr. Barwell, "such as brandy, ammonia, or wine, though decidedly useful in their place, have not such effect in restoring circulation, and exciting the system to greater action, as in collapse from other disease; indeed, considering the difference of its cause in this and in other maladies, it is not to be expected that they would be as beneficial; for prostration usually occurs in consequence of nervous shock, and consequent loss of nervous power; therefore stimuli which act upon that system are naturally, in those cases, such as would benefit. But in this disease there is comparatively little loss of nervous power; in fact, with so great disturbance of the circulation, the retention of nervous power is marvellous. Our remedies ought not, therefore, to be directed through that system, but we should, if possible, find some means of acting on and recalling the circulation, without exciting the nervous centres; and the best mode of doing this is by external heat. This principle of combating the deadly cold collapse was not found or recognised at St. Thomas's until after several cases had been treated at the hospital, and the general inefficacy of medicines or of stimulants proved. Though a certain number under the treatment then adopted recovered, still the whole result was unsatisfactory: thus, of twenty-eight cases of perfect collapse, before external heat was used, seven only recovered—a very small proportion; but, after this was employed, sixty-one patients were treated by some mode in which this formed an essential part; and of these, twenty-seven recovered, or not very far from half the whole number." (p. 97.)

Did space permit, I could adduce much evidence of the same description, in addition to that which has now been quoted. In fact, I could show that the success which many have ascribed to favourite pharmaceutical nostrums, ought, with much greater probability, if not with absolute certainty, to be ascribed to the external warmth employed along with the drugs.

Having now glanced at the general principles upon which medicines ought to be employed in the treatment of cholera, I would now remark, that I have not enumerated every drug which may be usefully employed, and have selected those with the operation of which I am personally most familiar. This much, however, may be added; that they are good types of the respective classes of remedies to which they belong.

The formulæ to be adopted must of course be varied in accordance with the circumstances of each case; and it is by a ready power of modifying these formulæ, that the skill of the practitioner is displayed. The formulæ cannot be too simple. No therapeutic advantages flow from the multiplicity of ingredients; and by administering remedies for the purposes of clinical study, as well as of cure, it is obviously necessary not to give more than one medicine, or one class of medicines, at the same time.

The following medicines possess in a high degree the power of arresting the serous diarrhoea, which generally precedes collapse by a good many hours, and which is the immediate cause of that collapse as well as of the cramps:

Creasote;
Turpentine;
Sulphuric acid;
Nitrous acid and nitro-sulphuric acid;
Nitrate of silver;
Quinine;
Gallic acid;
Alum; and
Acetate of lead.

1. *Creasote*. Some patients refuse to take creasote, from a dislike to its odour; but if one or two doses of two or three drops can be taken every hour or two hours, in mucilage, I prefer it to any other means of cure in serous purging. It hardly ever fails.

2. *Turpentine* may be used in place of creasote, in doses of ten minims. I have in several cases of diarrhoea found it quite successful.

3. *Sulphuric Acid*. The use of this acid in diarrhoea is by no means new. The late Dr. Anthony Todd Thomson, in his *Dispensatory* (Edit. 1837, p. 762), wrote as follows: "When combined with mucilages, it has been beneficially given in passive diarrhoea, operating on the relaxed nervous coat of the intestine as an astringent. The usual dose is from ten to thirty minims, but this dose may be very often repeated." In later years, its use has been revived; and several writers in the various medical periodicals have spoken in high terms of its efficacy. Among these I may mention Mr. W. I. Cox of Kensal Town, who has also employed it in cholera; (*Lancet*, for August, September, and October 1849, etc.); Mr. W. Griffith of Eaton Square, (*Ibid.*, Oct. 4th, 1851); Dr. G. B. Payne; Dr. Miller of Stoke Newington; Mr. Edgar Sheppard of Enfield (*Provincial Medical and Surgical Journal* for September 15th, 1852, and *ASSOCIATION JOURNAL* for March 18th, 1853); and several other practitioners. To Mr. W. I. Cox is due, as far as I am aware, the merit of having first employed sulphuric acid in the treatment of cholera. In a tabular view of the result of treatment of ninety cases, given by him in the *Lancet* for January 26th, 1850, five are mentioned as having been treated with sulphuric acid, generally in combination with Dr. Ayre's method. Four of the cases so treated recovered; but we can scarcely draw a conclusion from so small a number.

Dr. Fuller, of St. George's Hospital, in a paper lately published in the *Medical Times and Gazette*, speaks in high terms of the efficacy of sulphuric acid in arresting diarrhoea. In bilious diarrhoea, and in certain chronic diarrhoeas, he says it is of little or no avail; but in epidemic diarrhoea, in "acute autumnal diarrhoea", and in more decided choleraic diarrhoea, he has known no single instance of its failure. He gives it in doses of half a drachm mixed with water every twenty minutes or oftener; and the effects produced are described as remarkable; heat returns to the extremities; the nausea and vomiting cease; the purging is stayed; the cramps subside; perspirations generally break out; the tongue becomes moist and slightly coated; the intestinal evacuations become healthy; and the pulse regains its normal steadiness.

In epidemic cholera, Dr. Fuller has had no experience in the use of this remedy. He would give it in doses of ℥xl or 3j, five or six times in an hour, simply mixed with water; and he is opposed to the employment at the same time of brandy or any strong flavoured stimulant or carminative. Calomel, if it is thought necessary, may be given at the same time with, or after the acid. Mustard, bran, or other warm poultices or fomentations, may be applied; they usually afford relief. From the prompt action of sulphuric acid in arresting diarrhoea, Dr. Fuller expresses great hopes as to its superiority in cholera over other medicines which require a longer time for their action.

4. *Nitrous Acid and Nitro-Sulphuric Acid*. Mr. W. J. Anderson, in the *ASSOCIATION JOURNAL* of Nov. 4, 1853, recommends a combination of nitrous acid and sulphuric acid. He says: "Can a remedy be found which will readily yield up its oxygen, and supply that element to the impure blood; and at the same time, by its astringent properties,

tend to check the enormous exudation which takes place from the mucous surface of the intestinal canal? In our present state of knowledge, some of the mineral acids appear to be the best adapted to this purpose; and, for certain reasons about to be explained, a combination of nitric with sulphuric acid seems to me to be preferable to any other. The acid should be administered in tolerably full doses, and repeated at intervals varying according to the nature and urgency of the case. For an adult, we may give *acidi sulphurici diluti* f. 3ij, *acidi nitrici diluti* f. 3j in a six ounce mixture, an ounce being the dose for an adult.

Mr. Hope, of Chatham, in the *Edin. Med. and Surg. Journal* of July 1826, recommended nitrous acid in cholera. He spoke strongly of the efficacy of the following mixture:

R *Acidi nitrosi* 3j.
Misturæ camphoræ 3viii.

Misce, et adde tincturæ opii ʒij.

Of this one-fourth is to be taken every three or four hours. Mr. Whiteman, of Putney, informs me that he finds nitrous acid so prompt and so satisfactory a remedy in epidemic diarrhoea, that he trusts to it in preference to every other medicine. He often combines with it a little laudanum, but, in the majority of cases, he uses the acid alone. I have not used nitrous acid in diarrhoea or cholera; but I have no doubt as to its value in arresting the discharges.

5. *Nitrate of Silver* I have not given in cholera and diarrhoea, except in the form of enema. It is valuable in this form. My experience is too limited to enable me to compare the efficiency of enemata of nitrate of silver with enemata of acetate of lead, and of alum.

Dr. Lever and Dr. Aitken are the principal English writers who advocate the use of nitrate of silver in cholera and diarrhoea. On the continent, the authorities by whom it is recommended are Hirsch, Canstatt, Boudin, Bouchardat, and Trousseau. Dr. Charles Lever, in 1832, extolled the nitrate of silver as a remedy in cholera. In a forlorn case, he administered thirty grains dissolved in three ounces of distilled water, which the patient swallowed at once. She lay quiet for six minutes, when she vomited a small quantity of whitish turbid fluid. She had no return of the vomiting, fell asleep, and recovered. [*Johnson's Medical-Chirurgical Review*, Oct. 1834, p. 444.] I give ten grains in half a pint of water as an enema. Hirsch prescribed it in the form of mixture; and I am sure that it is a safe medicine in this form, as I have given it internally in other diseases, dissolved in abundance of water. The danger lies in giving the medicine in too concentrated a form.

6. *Quinine*. Of the power of quinine to check epidemic diarrhoea, and to thus arrest cholera in what may be regarded as its first stage, I feel well assured, from an extensive use of the remedy. It is true that I have generally combined it with sulphuric acid, or with iron, and sometimes with both; so that my facts are not available for the purpose of accurately determining the value of the quinine given alone. Dr. James Bird and others have, however, from ampler data, arrived at the same conclusion. Dr. Mandl, in the *Gazette Médicale* of October 29th, p. 682, speaking of the importance of checking the diarrhoea which he has generally found in the initiatory stage of cholera, says, "the most powerful means of arresting epidemic diarrhoea is by administering disulphate of quinine in doses of ten centigrammes (a grain and a half) every two hours." He says that he has seen cases of cholera, in which opium and injections had failed to arrest the discharge from the bowels, cured by quinine in twenty-four hours. Dr. Charles Bell, who has written so ably in favour of the doctrine that cholera is a fever of a remittent or intermittent type, naturally advises quinine. He says: "If asked what I should do in a case of cholera, I should answer, that that depended very much on the stage in which I found my patient; but, in all cases and in all stages, I should certainly give a largely diluted solution of some salts of iron and quinine, with a view to counteract the morbid inactivity of capillary congestion, and repeat it as often as the patient would drink of it, till warmth was restored." The practice is, there can be

little doubt, correct; but it is equally probable that it is a method well calculated to stop the diarrhoea, which Dr. Bell strangely considers salutary. He makes this dangerous announcement:—"Diarrhoea is a natural mode of relief to congestion, and thereby tends to the prolongation of life." The hæmorrhage from the stomach thrown up as black vomit in yellow fever, is nature's mode of relieving congestion; but it is not a salutary hæmorrhage. Within certain limits, a serous or a sero-sanguineous discharge may be harmless, or even useful; but in as much as it is physically impossible for the blood to circulate when it has been deprived of its serum, so is it imperative upon the practitioner to restrain the serous evacuations of cholera.

7 and 8. *Gallic Acid and Alum*. I have often used these remedies in the diarrhoea of phthisis, and occasionally in epidemic cholera. They are less to be relied on as means for arresting serous diarrhoea than creasote and the mineral acids. They are not superior, and hardly equal, to logwood and catechu, as mere astringents; but I know that some authors regard them as especially the astringents to be used in cholera and serous diarrhoea.

9. *Acetate of Lead* may be used internally alone, or in combination with opium. It is generally a prompt astringent when used in the form of enema.

I have not space to enter upon a consideration of all of several reasonable methods of treatment which have attracted the attention of the profession, and deserve to be spoken of with respect. I can only notice one of them at present.

The sulphur plan, as advocated by Mr. Grove of Wandsworth, has evidence in its favour, though I do not think that the theoretical ground—the fungus theory of cholera—upon which it is advocated, is tenable. Mr. Grove uses the following formula:—

R *Sulphuris precipitati* 3j.
Sodæ bicarbonatis 3j.
Sp. lavandulæ compositi 3vj.
Aquæ q. s. ut fiat mistura ʒiij.

A teaspoonful of this is taken every half hour or every quarter of an hour. Mr. Grove informs me that the effect of the medicine is to restore warmth, and promptly to check the serous discharges.

I believe Mr. Blacklock was the first author who recommended sulphur as a remedy for cholera. Although I have no personal experience of its virtues, I may quote, in connexion with this subject, the following passage from a letter dated September 22, 1849, which I received from a non-medical friend residing in Edinburgh:—

"I saw a man to-day from the south mairs, who told me that his wife and he, as well as many of the people of his remote landward parish, had been very unwell; and, from the symptoms which he mentioned, it was clear that they had suffered from cholera, and had been saved from it. They had no medical man near them, and got no medical attendance; yet there were no deaths. As soon as they found cramps come over them, they took a teaspoonful of powdered brimstone, or sometimes the flowers of sulphur, mixed with a little whiskey, to which was added water, if the sick could not otherwise swallow the dose. The man described the cure as certain and very rapid. Try this on the London folks; it may serve the afflicted, and do you much good."

Mitchell says that, "the sulphureous localities of the sickly island of St. Lucia are its only salubrious places. Cities, too, which abound in sulphur products.....enjoy an immunity from ague, for which they are everywhere noted. Immediately around the sulphur works, and factories for making gunpowder and sulphuric acid, the vegetation and the ague disappear together." To this we may add, that, in 1849, during the bombardment of Rome, that city suffered much less than usual from malarious fevers,—a fact which induced Mr. Walker to recommend cannonading, and the discharge of fireworks, as measures likely to ward off, or prevent the spread of, cholera. The rushing of columns of air, caused by the production of a vacuum, is, however, the more probable explanation of the benefits (if any) which

resulted from the cannonade. Mr. Blacklock (Madras, 1848) says: "I hope yet to see the day when sulphur, in small quantities, will be regularly issued to every soldier in the field, in India, say forty grains per day, while actually marching, and twenty grains per day, during halts, as a sure way of warding off this terrible disease; and I have a firm belief that sulphur, so employed, will be as effectual in banishing cholera from our armies, as lime-juice has been in eradicating scurvy from our fleets."

Mr. Grove quotes the following curious passage from the *London Practice of Physic*—a work published in 1692:—"In the year 1670, about the autumnal equinox, a world of people here were seized with a most dangerous flux (though without blood), and joined with a cruel vomiting, which presently caused great faintings and a total decay of strength. For the cure of this disease, no evacuation did good; nay, bleeding, vomiting, and purging did hurt: only cordials, and those of the hottest nature, to wit, such as abounded with *spirit and sulphur*, did good." (p. 22.) From this, it would appear that the whiskey and sulphur treatment of the south muirs of Scotland is an old tradition.

Manec administered sulphur in all possible forms, in his treatment of Cholera in the Salpêtrière in 1849.

Sulphur is a stimulant of the capillary circulation, and so is camphor—one of our best remedies against collapse. Perhaps the combination of the sulphur with hydrogen is the cause of the augmented heat in the surface of those who take the former in repeated doses. The characteristically offensive smell of sulphuretted hydrogen gas is sufficient proof that this chemical action does take place. The therapeutic action of sulphur is, however, yet open to investigation.

The treatment of cholera cannot be reduced to any routine formulary, but ought to be adapted to the particular condition of each patient in each stage of the disease.

The principal indications of treatment may be thus summed up:

1. The "rice-water" vomit and purging require to be energetically subdued by quinine, sulphuric and other acids, creasote, nitrate of silver, and such like remedies.
2. In actual and threatened collapse, external warmth, stimulant embrocations, and those internal stimulants which act on the capillaries, are of signal benefit.
3. In reaction, and during convalescence, local inflammations and congestions require to be guarded against or subdued; and rational means must be adopted to restore the secretions of the liver, kidneys, and skin, but particularly of the two former.
4. Lastly, though not of less importance, the character of the fever should be modified, and a repetition of the paroxysm guarded against, by change of air, or by the administration of quinine, which, in the majority of cases, from the existence of anæmia, ought to be conjoined with iron.

Putney, London, November 5, 1853.

REPORT OF THE READING PATHOLOGICAL SOCIETY.

By W. W. MOXHAY, Esq.

[Read June 28th, 1853.]

The annual retrospective address of the Reading Pathological Society contains many cases of interest; and will serve to shew how great an amount of information may be derived from attendance on such meetings. The cases are arranged under the heads of the various systems diseased.

DISEASES OF THE NERVOUS SYSTEM.

SOFTENING OF THE SPINAL CORD: DEATH. By T. L. WALFORD, Esq. (June 30th, 1852). Mr. Walford mentioned the case of Edward Gore, aged 51, who got wet on the 9th October 1852, and lay asleep for some time in an outhouse in his wet clothes. On the 11th, on rising to go to work,

he found great difficulty in moving his legs. On the 12th, his arms also became weak, and he became restless, constantly requesting to be lifted out of bed, etc. On the 20th, articulation became difficult and indistinct; his breathing also became difficult and gasping; his voice dwindled to a whisper; and he expired on the 21st.

Examination of the Body. The spinal marrow was found softened in parts, in some being quite diffuent, and there was much fluid in the theca vertebralis. This case seemed very similar to that of the late Mr. Dunn. He was exposed to cold; numbness and loss of power in the feet began soon after, with the addition of pain along the sciatic nerves, and in the sacrum. The paralysis gradually crept upwards, and ultimately killed him by suffocation, from the intercostal and phrenic nerves being implicated. A *post mortem* examination would doubtless have revealed a similar state of things to that found in Mr. Walford's case.

TETANOID DISEASE. By F. A. BULLEY, Esq. (Nov. 24th, 1852.) George Chilvers, aged 19, applied at Mr. Bulley's house on the evening of April 26th, with painful tonic contraction of the forefinger and thumb of the left hand, the result of a wound which he had received four days previously. He was told by a fellow-servant that he might have locked-jaw; and soon afterwards, in gaping, his mouth became fixed in the open position, and he could not shut it again for five minutes. Tobacco steeped in brandy was applied, and the muscles relaxed. Soon afterwards, the boy took hold of a broom, and the hand became so firmly clenched on the handle, that he could not let it go for some time. He seemed to have been much frightened by something a druggist practising in the town said to him, and applied in consequence at Mr. Bulley's surgery. Mr. Bulley found a slight cut between the thumb and forefinger nearly cicatrised. The countenance expressed alarm; the pulse was quick, but feeble; and the skin pale and cold. The chief complaint, on the patient's part, was that the jaw, finger, and thumb, were very stiff. Mr. Bulley was about to pass a few mild shocks of electro-galvanism from the brachial plexus downwards, and had just adjusted the poles of a battery for that purpose, when the boy swooned. On his recovery from this state, muscular twitchings took place in the body and limbs, and the whole became convulsed, the trunk being violently bent backwards as in opisthotomos, so that three men were required to hold him. Some froth oozed from his mouth. The convulsions recurred frequently, and the boy seemed partially insensible in the intervals. He spoke little, and with difficulty. The skin remained cold and bathed in cold perspiration, and the pulse very feeble. The muscular disturbance began to diminish in about four hours, when, a conversation being held in the patient's hearing about procuring a shutter, and the necessity of conveying him on it to the hospital, it ceased altogether, and he was removed in a state of fatigue to that institution. He subsequently complained of some pain up the arm, and the finger and thumb remained contracted into the palm of the hand for some days. He had, however, no further convulsions, and was soon discharged well.

DISEASE RESEMBLING HYDROPHOBIA. By F. A. BULLEY, Esq. (Nov. 24th, 1852.) Mr. Bulley was called on the 2nd September, 1851, at 8 P.M., to James Woodlands, aged 28, a man of intensely melancholy countenance. He found him laid on some bedding in a yard in Friar Street, with several people holding him, whilst his body and limbs were affected with violent contortions. These had been going on for some time, and recurred every five or ten minutes. In the intervals, he was moody, frequently sighed, and was obstinately silent. The jaws were firmly closed, except when a teaspoon or cup containing fluid was brought near him. He in this case made attempts to bite at the article, and his countenance became expressive of great horror; he would utter a low groan, his features relaxed from their malignant expression, muscular contractions ensued, beginning in the face and extending over the whole body, which, at length, was thrown into convulsions, so violent

as to require four or five men to prevent injury. Mr. Bulley, thinking the case one of epileptic seizure, ordered water to be brought, for the purpose of dashing some on his face. A little made a splash on the stones; intense horror was shown by the man; he endeavoured to rise, and snapped at Mr. Bulley like a dog, and the convulsions became more violent. These ceased about half-past one A.M., when the hospital was mentioned, and the patient firmly ordered to get up. He walked with assistance. Mr. Bulley mentioned, that, upon turning on a water-tap which was in the court, the greatest horror was shown by the man; and even spitting on the ground near him produced a similar result, and excited a convulsion. He stated the extreme resemblance of this case to one of hydrophobia he had seen in London; and how much alarmed he was on this account for the result, especially as there were some wounds on the patient's hand, of which no history could be obtained. After the removal to the hospital, no further symptoms were noticed, except the moodiness of countenance and extreme melancholy. It was found on inquiry, that the man had been bitten by a dog; but he was quite a child at the time, and the dog was a healthy one. He had, however, thought much of this lately; and his fellow-workmen and he had talked much of hydrophobia. It was also found that he had been lately disappointed in love, which had preyed much on his mind. He had been seen on the evening of his seizure to walk in a staggering manner, and subsequently to fall insensible. No evidence was given of his having been drinking. The only treatment in the hospital was a mercurial laxative or two, as his tongue was dirty and his bowels confined. He left in a few days.

Mr. Bulley said that, no doubt, in these two cases, fear was the exciting cause of the attacks of convulsion; the nervous system being peculiarly predisposed to receive such an impression, the circulating system became depressed, as indicated by the cold clammy skin, and feeble pulse. The internal organs, as it were, became clogged, and the capillaries deserted by the blood; the convulsive movements which ensued were, he thought, a cure for this state of things, by restoring the equilibrium of the circulation. He leaned to the idea of the first case being really one of tetanus; but no opium nor other medical treatment having been used to check the salutary spasms, they had thereby opportunity given them to relieve the internal congestion. Mr. Bulley promised on some future occasion to give to the society more fully his ideas on convulsions. I may remark on these two interesting cases, that I thought them to bear a general resemblance to attacks of hysteria, as seen in the female, and also occasionally (though the derivation of the term makes it an awkward one to use) in the male. There were the same causes in operation, which will produce an attack of hysterical convulsion; viz., a state of mental depression and fright. There were the biting and endeavour to injure the bystanders, and the throwing about of the limbs, as if the movements were to a great extent under the command of the will: these symptoms I find mentioned in my account of both cases. There were the same obstinate silence, the apparent insensibility, but real consciousness of what was said and done near them: as witness the abrupt termination of the convulsions, on mention being made of the hospital. The fear of water, I apprehend, in the second case, was due to the one peculiar source of disquietude, i.e., the fear of hydrophobia; the mind having being impressed with the notion; that dread of water was one of the essential symptoms of the disease. The peculiar countenance of tetanus was absent, I think, in the first case, as also the peculiar lasting rigidity of the muscles, especially of the masseters and pterygoids, which, had it been present, would have rendered biting and snapping perfectly impossible. Was the lasting contraction of the flexor muscles of the thumb and forefinger different from the irregular vagaries of muscular action so frequently seen in hysteria?

DISEASE OF THE BRAIN IN A SYPHILITIC PATIENT: DEATH. By T. L. WALFORD, Esq. (June 30th, 1852.) The subject was a woman, aged 50, who had contracted

syphilis four years previously. She had since complained of pain in the head, and was, a day or two since, said to have had a fit. She began to turn about restlessly in bed; she could not be got to take medicine; and took little or no food. She answered in monosyllables. There was great difficulty in swallowing. The intelligence was neither exalted nor depressed. The opinion of the Society was in support of the existence of nodes pressing on the brain, and in favour of the use of mercury internally, as well as the application of mercurial ointment to the blistered scalp.

The *post mortem* examination in this case, as subsequently related by Mr. Walford, revealed opacity of the membranes of the brain, serous effusion at the base, and softening of the right optic thalamus and other central parts.

Mr. MAY mentioned the case of a military man, who had complained of severe fixed pain in the head for a length of time, and he was paralytic; the origin of these symptoms being syphilis. He died; and, on pressing upon the painful spot, the bone was found to be destroyed. There would probably have been an ulcer through before long.

DISEASE OF THE PONS VAROLII. By G. MAY, Esq. (Sept. 29th, 1852.) The patient was a girl, Miss C., aged 9. About six months before death, she had fallen from a swing, and had struck the back of her head. In a fortnight, she began to speak badly; then she was sick, especially in the morning; symptoms of chorea followed; she occasionally fell down; etc. At this time, she had convergent squint of the eyes, chiefly the right. She gradually lost general power, and was confined to bed for three months before death, having paralysis of the right arm and leg. Both limbs were extended and stiff. The other side became gradually affected, but not to the same extent. Convulsions occurred occasionally; the intelligence, special senses, and sleep, remaining unaffected. She became more asthenic, convulsed, and comatose, and sank by apnoea.

Examination of the Body. An abscess was found in the right side of the pons Varolii, with ulceration of its entire surface, and congestion of the membranes. The sixth or abducent nerve on the right side was destroyed; the left had also probably been destroyed. There were about four ounces of fluid in the ventricles. This case, Mr. May said, bore out Dr. Marshall Hall's views on the pathology of chorea, as he placed the seat of this disease in the pons Varolii.

DISEASES OF THE RESPIRATORY SYSTEM.

SUDDEN DEATHS IN PHTHISICAL PATIENTS. By T. L. WALFORD, Esq. (May 26th, 1853.) Mr. Walford mentioned that two phthysical patients under his care had died more suddenly than usual; one by bringing up a large quantity of blood; the other, an old man, by syncope.

Mr. MAY said, that the latter was not an unusual termination; the heart, participating in the general debility, being at last unable to carry on the circulation.

MASSSES OF COAGULATED MILK IN (ESOPHAGUS OF A CHILD. By G. D. BROWN, Esq. (May 25th, 1853.) Some specimens were exhibited by Mr. Brown of what he thought to be casts of the trachea and bronchi; they had been vomited under the use of an emetic, in a child, who had suffered from measles, and had croupy breathing and urgent dyspnoea. These symptoms ceased on the action of the emetic. The substances were white, greasy to the feel, and capable of being rubbed down between the finger and thumb.

Mr. WALFORD (and in this the Society coincided) thought these masses were portions of coagulated milk, which had filled the oesophagus, and so pressed on the trachea and larynx from behind.

Mr. BROWN was inclined to adopt this opinion, especially as the microscope showed oil-globules. There was no appearance of these masses being tubular; they were quite solid.

DISEASES OF THE DIGESTIVE SYSTEM.

EXPULSION OF TAPE-WORM FROM THE SMALL INTESTINE. By G. MAY, Esq. (Oct. 21st, 1852.) He reported a case of expulsion of tape-worm from the

lowed by castor-oil. The worm was subsequently examined microscopically by Mr. Goodwin; but he did not succeed in finding the head.

VOMITING AND EMACIATION DURING PREGNANCY. By E. WELLS, M.D. (Jan. 26th, 1853.) The patient was a lady whom Dr. Wells had visited in the Isle of Wight, in June 1852. She was then suffering from vomiting and anorexia. In July, emaciation had rapidly progressed, and tympanitis began. She was placed under the care of a homœopathic practitioner, who five months afterwards suspected pregnancy, and wished her to be removed to London. The uterus was then found to contain an eight months' fetus. She continued to lose flesh, though taking iced food; and one day she suddenly died, after a hearty meal. When the body was examined, marks of inflammation and ulceration were stated to have been found in the stomach; but there was no other organic disease. The curious points of this case were the obscurity of the signs of pregnancy; the persistence of emaciation, though abundance of nutriment was taken; and the difference in the character of the vomiting from that of ordinary pregnancy.

The members of the Society thought that the question which presented itself was, Whether, when the existence of pregnancy had been decided on, and was the presumable cause of the vomiting, emaciation, etc., premature labour should not have been induced?

CALCULI IMPACTED IN THE CYSTIC DUCT: DEATH. By I. HARRISON, Esq. (Nov. 23rd, 1852.) Mrs. P., a robust and healthy woman, aged 33, had been attended by Mr. Harrison several times, on account of severe bilious attacks, with much pain in the stomach, obstinate vomiting, and slight jaundice. She had married twice, and had become quickly pregnant by her second husband, but had had no children by the first. Seven days before her death, she was seized with vomiting, which continued until within two days of that event, nothing appearing to arrest it. She had also acute pain in the right hypochondrium. She rapidly became weak; the skin assumed a dirty yellow colour; and her expression became that of hebétude produced by poisoned blood. Delirium supervened, and she sank from asthenia. A blister to the epigastrium, calomel and opium, purgatives of tartarised soda, with pills of colocynth and hyoscyamus, constituted the treatment; the diet being beef-tea and brandy, and soda-water with lumps of ice in it. As to the diagnosis, Mr. Harrison remarked, that it was evident that the under surface of the liver was the part attacked. There was no tumour nor distension of the bowels.

Examination of the Body. The liver was found small, and slightly congested only; its structure being healthy. The gall-bladder was small, with a much thickened capsule; the ducts also were thickened. Two stones, of the size of peas, were impacted firmly in the cystic duct, which was much contracted in calibre. The hepatic and common ducts were pervious. The uterus contained a three months' fetus.

Mr. Harrison remarked that there was no obstacle to the flow of bile from the liver, so that the theory of obstruction to the passage of bile would not apply here. The best explanation he could offer was, that the continued irritation of the impacted calculi so acted on the liver, that its operations became suspended, and the blood, especially in the state of pregnancy, became poisoned. He thought that poisoned blood was the immediate cause of death.

OBSTRUCTION OF THE BOWELS: OPERATION FOR ARTIFICIAL ANUS: DEATH. By G. MAY, Esq. (April 20th, 1853.) This case is related in the ASSOCIATION JOURNAL for May 6th, 1853. The points of interest were, the capability of passing a long tube, twenty inches, *per rectum*; the consequent choosing of the cæcum as the seat of operation, and the revelation, by *post mortem* examination, of the interesting fact, that the stricture, which was produced by cancerous disease, existed only six inches from the anus, and that a portion of the intestine above falling, as it were, like a valve on the upper opening of the stricture, so perfectly closed it as thoroughly to prevent the feces from coming down,

though the tube could readily pass from below upwards. The operation was performed through the anterior abdominal parietes, with the effect of allowing a small quantity of feces to escape before death.

Mr. WALFORD objected to opening the cæcum, both on anatomical and on physiological grounds. The cutting into this part of the bowel, surrounded by peritoneum, involved a greater amount of risk than opening the descending colon from behind. The cæcum, he thought, performed an important part in the function of defæcation; and the colon could not be brought to empty itself here.

Mr. MAY, in reply, stated that the statistics of the operation, as given by Mr. C. Hawkins, did not show a great difference in mortality in favour of the posterior operation; and he (Mr. H.) seemed, in his comments on the cases tabulated by him, rather to prefer the anterior.

CASES OF OBSTRUCTION OF THE BOWELS: USE OF TOBACCO INJECTIONS. By E. H. PAYNE, Esq. Mr. PAYNE read the histories of three cases of obstruction of the bowels, in which he had used injections of tobacco. He attributed much to this remedy in the recovery of these patients. He had great objection to purgatives when there was obstinate vomiting; and he laid great stress on obtaining good tobacco, recommending highly the sort called Cavendish, as being less likely to be adulterated. He infused from twelve to twenty grains of this in a half pint of boiling water, for fifteen minutes.

CASE I. James G., aged 68, was seen by Mr. Payne, June 7th, 1830, in the evening. This patient had always enjoyed good health, but his bowels had lately been irregular; they had not acted, at the time of his being first seen, for five days. He vomited constantly; the abdomen was distended and uneasy on pressure, and he complained of its being tight; his countenance was anxious; the pulse was 90 and tolerably firm. He was bled to faintness; and calomel and opium with effervescing salines were ordered.

June 8th, *morning*. The bleeding gave him several hours comfortable sleep; he had no sickness. The vomiting, however, returned about the middle of the day with much pain; the pulse being 108 and weak. Everything was rejected by the stomach. He was ordered to have a hot poultice applied to the abdomen; and abstinence from fluids and a continuance in the use of the pills were enjoined.

Evening. The countenance was very anxious; he had vomiting of fecal matter; the pulse was 130; the abdomen tympanitic; he had constant hiccough. Mr. Payne ordered a tobacco injection (☉j. to Oss). It caused slight faintness; the patient had, however, afterwards, some relief from the pain; and his sickness abated. He had a wine-glass of sherry during the faintness; and was ordered to continue the pills every three hours. Another injection with fifteen grains of tobacco was used in six hours.

June 9th, *morning*. He had been sick twice only after the last injection; he had no hiccough; he had expelled some wind by anus. The countenance was improved; the pulse 94, weak. He was very thirsty. The injection was repeated, and the pills were continued.

Evening. He was easier; the belly was less tense; he was very thirsty. The injection was repeated; this was followed by free evacuation from the bowels; after which he speedily got well.

CASE II. Mrs. C., a corpulent, drinking woman, was seen by Mr. P., on Feb. 13th, 1832. Her countenance was anxious and sunken; the pulse 111, very weak; and the abdomen much distended. There was constant vomiting of stercoraceous matter, with hiccough; the pain had been very great, but she seemed sinking; her skin was cold and moist. She had been under treatment for a week, for constipation of the bowels. Mr. Payne ordered the following pills to be taken every three hours:

R Calomelanos gr. ij.
Camphoræ gr. i.
Opii gr. i. M.

The patient was directed to abstain from fluid. A tobacco injection (☉j. to Oss.) was used. This woman passed some

flatus on the 15th; and, in the night, a large amount was forcibly expelled, which was followed by an immense foetid evacuation, with some bloody serum. The calomel and opium had been continued, and she had had five more enemata administered, the quantity of tobacco used at a time being from twelve to fifteen grains only, on account of her extreme weakness. Wine and brandy were likewise given. She nearly sank after the evacuation; but, under the use of brandy and opium, with the injection of two drachms of compound tincture of camphor, she gradually recovered, the peritoneal covering of the abdomen being somewhat thickened.

CASE III. Mrs. S., a short, stout, thickset washerwoman, was seen by Mr. Payne's assistant on April 2nd, 1838, having then, after a week's constipation, been suddenly seized, at the wash tub, with violent pains in the abdomen. She was bled to six ounces, and croton oil with a senna mixture was ordered; everything was, however, vomited. Afterwards, Mr. Payne himself saw her. The pains were then very violent, and the sickness was excessive; the pulse was 136, full, and firm. He bled her to twenty-six ounces with much relief to the pain and the vomiting. He ordered two grains of calomel and one of opium every three hours. No fluid was allowed.

On April 3rd, she was again bled to faintness, the sickness and pain being as violent as ever, and feculent matter being ejected. This woman sank into a very feeble condition.

On April 14th, after a tobacco injection, flatus escaped with a loud noise, which was followed by stools, great faintness, and produced the flow of bloody serum. She recovered from this faintness under the same treatment as in the previous case; the peritoneum remaining also thickened. She had marked tenderness above the ileum on the left side; two tobacco enemata were administered, the calomel and opium having been continued only up to the 6th, on account of the patient's refusal to take them. She, as well as the second woman, often asked for the injection.

Mr. Payne had been led to abstain from violent means for getting the bowels open, by having, many years ago, witnessed a case, in which the transverse colon was borne down upon the uterus by the weight of a pound and a half of fluid mercury, the administration of which had formed part of the treatment. He determined for the future to have recourse to sedatives, and used the tobacco injection on this account. He only allowed a mild aperient after the sickness had subsided. He thought that every addition of fluid in the distended state of the bowels was extremely injurious, and delayed relief.

SCIRRUS OF THE PANCREAS. By G. MAY, Esq. The tumour had been felt, during life, near the region of the pylorus and towards the umbilicus; it was hard, but not defined; was deep seated, and slightly tender. The prominent symptoms had been, shooting pains through from the abdomen to the back, occasional vomiting, a disgusting taste in the mouth, loathing of food, and flatulent distension. The patient died asthenic.

Examination of the Body. The pancreas was found enlarged and nodulated at its head, and infiltrated with scirrhous deposit. Ulceration had commenced in the transverse duodenum posteriorly. The liver contained nodules of scirrho-encephaloid deposit, and one or two existed in the lungs.

CONSTRICTION OF THE ŒSOPHAGUS. By R. T. WOODHOUSE, M.D. (May 25th, 1853.) A lady, aged 43, who had long suffered from dysmenorrhœa, and had some stomach derangements which had generally yielded to alkalies. About eighteen months ago, she complained of pain in swallowing, referred to the lower third of the sternum. Emaciation ensued from the inability to swallow sufficient nourishment, the appetite being craving. She was relieved by anodynes, and partly nourished by asses' milk and injections of beef-tea. The passing of bougies was recommended by a medical friend in London, but another disapproved of this proceeding. She latterly complained of excruciating pain in the mammae, awakening her about one or two o'clock in the morning, notwithstanding large doses of morphia at

night. A distinct bruit was heard behind, in the situation of the aorta, between the ninth and twelfth dorsal vertebræ. She died on May 20th.

Examination after Death. There was extreme emaciation, but the mammae were of full size. The œsophagus was slightly constricted below the cricoid cartilage; and there was an irregular thickened opening, which led into a small abscess filled with sanious offensive matter. The coats of the tube were infiltrated with a dense greyish deposit, which narrowed the calibre, so as scarcely to admit the finger. About the third or fourth dorsal vertebræ, the tube dilated into a large pouch, containing the same sanious fluid; this sac extended to the right of the spine, and separated the pleura from the root of the lung on this side. Just above the cardiac orifice of the stomach, there was a dense ring of adventitious deposit, about half an inch in thickness, through which, however, the finger passed readily into the stomach. The large pouch presented internally a number of nodulations, irregular in shape. The stomach was slightly congested; the pylorus was healthy. A lymphatic gland at the head of the pancreas presented some malignant deposit. The cervix uteri was hypertrophied, and the os contracted. There was a hard calcareous mass, as large as a pullet's egg, at the situation of a bronchocele which had been cured by iodine.

This case showed the value of beef-tea injections in sustaining life for a long period; the patient having been mainly supported by this means for twelve months. The pain in the mammae Dr. Woodhouse explained by the pressure of the thoracic abscess on the intercostal nerves.

The following case illustrates the necessity of extreme caution in the use of bougies. A man had dysphagia, hoarseness, cough, and hæmoptysis, but only to a moderate amount. After some time, an aneurism was diagnosed, on account of dulness under the upper part of the sternum, and to the right of it, with impulse, and an occasional indistinct bruit. The man died; and a small aneurism was seen, which opened into the left bronchus, and also into the œsophagus, by large apertures with rounded edges, showing that they had existed some time. The free flow of blood had apparently been prevented by clots blocking up the apertures. The opening into the œsophagus would have readily admitted the end of a bougie. Mr. May has reported a similar case. On the other hand, in cases of apparent obstruction of the œsophagus, the passing of bougies has not only been not detrimental, but has afforded the greatest relief.

The value of beef-tea injections is further shown in the case of a child, who had been burnt on the shoulder. This burn was followed by erysipelas of the whole trunk; he had diarrhœa, and obstinate vomiting of everything given; the ejecta being like coffee-grounds. The features were sunk, and the pulse was almost imperceptible. He appeared, in fact, to be sinking. A beef-tea injection, containing two drops of laudanum, was ordered to be given every four hours; and collodion was painted freely over the reddened skin. The vomiting and diarrhœa ceased as if by magic; and, after a few injections, the child was able to take nourishment by the mouth, and recovered from its perilous condition.

Reading, September 1858.

[To be continued.]

ON CHANGE OF SIGHT AS PREMONITORY OF HARD CATARACT.

By W. WHITE COOPER, F.R.C.S., Ophthalmic Surgeon to St. Mary's Hospital, and Senior Surgeon to the North London Eye Infirmary.

In the second edition of my work *On Near Sight, and on the Eye, etc.*, reference is made to a class of cases of rare occurrence—cases in which persons, having been presbyopic, and having used convex glasses, as they advanced in years recover natural vision, or become near-sighted. I

avoided expressing a positive opinion as to the cause of this; but I have now been led to differ from the conclusions entertained by Mr. Ware and M. Sichel. Mr. Ware explained the phenomenon on the supposition that, in consequence of absorption of a portion of the vitreous humour, the sides of the sclerotica were pressed inwards by the action of the muscles, the effect being to lengthen the axis of the eye, by which the aberration becomes corrected. M. Sichel considers this apparent return of the power of accommodation as in reality a shortening of the visual focus, caused by the use of too strong convex glasses.

I have recently had the opportunity of studying four cases of this description, and have quite satisfied myself that, in them at least, the change from presbyopic to myopic sight was premonitory of hard cataract.

I have observed that myopic persons, who become affected with cataract, increase the power of their glasses to the very highest numbers, even to No. 14. It is often considered that the need of higher and higher glasses under these circumstances is a delusion, and that the mere fact of the vision becoming more and more imperfect leads the patients to seek increased assistance in stronger glasses; yet, as the highest concave glasses diminish objects to almost microscopic minuteness, it was difficult to believe that they really afforded assistance. Observation has, however, led me to believe that the assistance was not imaginary; and the reason is probably this. In all cases of hard lenticular cataract, the crystalline lens becomes closer and denser in structure, and generally rather flattened in shape; but the flattening is in some cases less in proportion than the increase of density. By this increase of density, the refractive power is altered, and consequently the focal distance is shortened; so that a myopic eye, which formerly derived sufficient assistance from lenses Nos. 6 or 8, needs Nos. 12 or 14 for reading, or seeing moderately distant objects.

To an analogous change* I refer many of those singular cases in which old persons lay aside their convex presbyopic glasses, being able to do without them, or find themselves under the necessity of using concave or myopic glasses. The increase in density may be sufficient to counteract the changes which had previously diminished the refractive power, and to restore to the eye its natural focal distance; or it may go a little further, and cause the image to be formed in front of the retina as in near sighted persons. Such a change in the density is not necessarily attended with so much diminution of the transparency of the lens as to materially interfere with vision, though I believe the sight is always a little impaired, which the patient properly sets down to the account of old age; but, in many cases, the change goes on; the lens becomes shrunken and amber coloured; and the patient is sooner or later pronounced to have hard cataract.

The characteristics of the cases which I have seen have been these. A person, about the middle period of life, has taken to glasses, which have been increased in power as years rolled on. He has numbered perhaps seventy summers, when he finds the high powers less agreeable than the lower, which are resumed; but, after a time, they too, strain the eyes. Perhaps glasses are altogether laid aside, and the fortunate individual receives the congratulations of his friends on his renewed juvenility. In some cases, the sight is far from clear, and objects are held near the eyes to be discerned; accidentally, perhaps, he looks through a concave glass of low power, and is agreeably surprised at finding his sight improved. As these symptoms occur in advanced life, the persons may die before other phenomena present themselves, and the true nature of the case may never be discovered. But if the parties live, the sight, sooner or later, becomes little by little obscured, and the characteristic symptoms of hard lenticular cataract are established. I have often been struck with the slow progress of some of

these cataracts. During the last ten years I have, from time to time, examined the eyes of a clergyman who consulted me in 1843, for slight imperfection of vision. In his right lens two small striae were then visible; in the left lens there were three; the nature of the case was explained to him, he has taken great care of his eyes, and although there is now a general haze in both lenses, he has sufficiently useful vision to perform his clerical duties. Another patient, a physician, has had cataract fully formed in the left eye for six years, and incipient cataract has existed in the right for nearly the same time; but it has been so stationary that he still reads and writes.

The formation of cataract, then, may be so gradual that it may have made considerable progress before the patient will admit that his sight is much impaired; I have known patients almost angrily protest that their sight was good—not quite so sharp as it used to be, but still very good—when decided cataracts were plainly visible. The fear of the proposition of an operation may lead them to make the best of matters, but there is much self deception in many cases.

In the four last cases of sight changed from presbyopia to myopia, which have fallen under my observation, careful inspection, at intervals of two or three months, has traced the change of structure from the first faint indications to the unmistakable characteristics of hard, lenticular cataract; and, as a general rule, such cases should be carefully watched, for it commonly happens that persons who appear to have recovered their pristine sight in the manner described, are disposed to take liberties with it and to use their eyes more than is prudent. They should be warned against this; for though art can do little directly to arrest the progress of cataract, congestive action of the eyes may be prevented by the patient abstaining from over exertion of those organs, especially by artificial light; and he ought to be careful so to arrange his position when reading or writing, that the object on which he is engaged should be well illuminated, but the eyes kept in the shade, and protected from the injurious stimulus of heat and glare. He should always use the blackest ink, write a bold hand, and above all avoid reading small and indistinct type.

19, Berkeley Square, October 1853.

TWIN PREGNANCY: ABORTION OF ONE FŒTUS IN THE THIRD MONTH, THE OTHER ATTAINING THE FULL PERIOD.

BY G. G. BROWN, Esq.

Mrs. W., aged 30, a dress-maker, had suffered, up to the time of her marriage, about twelve months since, from irregular menstruation, vicarious with which there was occasionally excessive intestinal mucous irritation. She has also suffered for some two or three years from spinal irritability, slight lateral curvature of the spine; and, when engaged more than usual in her business, she had, as the result of the disordered condition of the spinal column, severe spasmodic contraction of the extensors of the hand and forearm. These symptoms were always relieved by a tonic plan of treatment, rest from work, counter-irritation, sea air and bathing, and the exhibition of chalybeates. By the advice of one of our most talented provincial physicians, she got the common spine support, with crutches for the arms, etc., in the hope that she might resume her business; and its adoption gave very decided relief to the muscular contractions, but was shortly succeeded by dyspnoea and cough, bearing a close analogy to spasmodic asthma, and relieved by the same class of remedies.

The catamenia, having ceased to flow on the 5th of January, 1853, were succeeded by the usual symptoms of pregnancy. On the 10th of April, I was summoned to my patient, when I found she had aborted of a fœtus of the size and development of ten weeks, or thereabouts. Some kind of clot (which had been disposed of) had preceded the

* Since this paper was written, I have conversed with a distinguished Viennese ophthalmologist, Dr. Meyr, and find that he had arrived at the same conclusions as myself, as to the nature of the cases in question.

escape of the fetus, and, I presume, contained the membranes and placental mass, as no subsequent clot or hæmorrhage followed it. On the following day, she was about again; and (looking at the delicate health of my patient) I congratulated her on getting so well through it.

From her miscarriage till the 6th of July, I did not visit my patient, but at this time was consulted by her on account of the large size of the abdomen, which she attributed to dropsy, or other visceral enlargement from disease. On making an external examination, I found a tumour of the size, and having the position of a gravid uterus at six months. On questioning her as to the symptom indicating fetal viability, she could not speak positively (being her first pregnancy), attributing such movements to flatus. Whilst observing to her that I should wish to test the presence of a second child by applying my cold hand to the abdomen, I, on the instant, felt what I could not mistake as the fetal movement, and, extraordinary as it appeared to my patient, gave my opinion accordingly. I have only to add, that her health had much improved since her miscarriage; the dyspnoea and cough had passed away, and she had taken nourishment with advantage to her strength.

On the 1st of October, the waters came away with very slight pains; and these continued at intervals, with some discharge of the same kind, till 4 A.M. of October 5th, when decided uterine contractions set in, and, at half-past nine A.M., she was delivered of a lively healthy male child, of the average dimensions of a nine months' gestation.

By a reference to Dr. Tyler Smith's method of calculating the period of pregnancy, it will be found that, by taking January 1st (the day when the last catamenia appeared) as the commencement of our reckoning, October 5th will be found as the tenth return of the catamenial period.

Stourport, Worcestershire, October 28th, 1853.

ASSOCIATION INTELLIGENCE.

MEDICO-ETHICAL COMMITTEE.

This Committee met in the Freemasons' Tavern on Thursday, November 3, at 3 P.M. The members present were Dr. Ogier Ward, of Kensington, W. H. Michael, Esq. of Swansea, Dr. Woodforde of Taunton, and J. S. Bartrum, Esq. of Bath. A sub-committee was appointed to prepare a draft code of ethical laws, to be forwarded to all the members of the Committee, and then discussed at a general meeting of the Committee to be held in January or February. The place of meeting was not fixed.

N.B. In the list of members of the Ethical Committee, published at p. 948, we omitted the name of Dr. Barclay of Leicester, Secretary for Leicestershire (Midland Branch).

METROPOLITAN COUNTIES BRANCH: PROCEEDINGS OF THE COMMITTEE ON GRATUITOUS MEDICAL SERVICES.

The members of the ASSOCIATION are aware that, at the annual meeting of this Branch, held in July last, Sir JOHN FORBES, M.D., D.C.L., the President, in the chair, the following resolution was carried unanimously:—"That a Committee be appointed to inquire into the evils which are said to flow to society and to the medical profession from the practice of giving gratuitous advice indiscriminately and unnecessarily." (*Vide JOURNAL*, July 22.) Eight gentlemen were appointed, with power to add to their number.

The Committee first met on the 5th of August, when Dr. Cormack was appointed Chairman, and Mr. Charles, Honorary Secretary. It was resolved to request several gentlemen to join the Committee. They for the most part acceded. A complete list of the Committee was published in the ASSOCIATION JOURNAL of Oct. 28th.

A sub-committee was appointed on the 5th August, "to arrange a plan of proceedings, to be submitted to the next meeting." This meeting took place at 3 P.M. in the Freemasons' Tavern, on the 3rd instant. The following members were present:—Henry

Ancell, Esq.; C. T. Carter, Esq.; Thos. Charles, Esq.; John Rose Cormack, M.D.; R. Payne Cotton, M.D.; Patrick Fraser, M.D.; A. Halley, M.D.; Henry Lee, Esq.; C. F. J. Lord, Esq.; W. O'Connor, M.D.; R. R. Robinson, Esq.; T. O. Ward, M.D.; and George Webster, M.D.

The chair having been taken by Dr. CORMACK, the sub-committee presented their report, including a series of queries, proposed to be extensively circulated amongst the members of the profession. The queries were discussed *seriatim*, and were unanimously adopted for circulation in the following form:—

1. Are you acquainted with the practical working of any medical charities? If so, state their names: the number of patients relieved annually, in doors and out doors: the annual expenditure in each: the salaries paid to legally qualified medical officers: also the number and denomination of medical officers giving their services gratuitously.

N.B. The last annual report, if forwarded to the Committee, will aid their inquiries.

2. State the classes or denominations of the poor whom you consider the proper recipients of gratuitous medical services in these institutions.

3. State the classes, orders, or denominations of the community habitually receiving gratuitous medical services in these institutions whom you consider *not* to be proper objects of charity, with any information you can append as to their circumstances and habits of life.

4. Give particular instances of the abuses (if any) of these charities.

5. State the character and efficiency of the gratuitous medical services rendered at these institutions,—such as the time bestowed by the medical officers; the average number of patients seen on each day by each officer, etc.

6. Are you acquainted with any facts relating to the system of gratuitous medical service by private practitioners? If so, state them, with any particulars calculated to aid the Committee in arriving at correct knowledge as to its extent and bearings.

7. State generally your opinions as to the effect of gratuitous medical services as at present afforded:

I. On the public:

II. On the Science of Medicine: and

III. On the profession in a moral, a social, and a pecuniary point of view.

Illustrate your opinions as much as possible by facts.

8. Mention the gratuitous medical services to your knowledge given by the profession to classes of society respecting whom *charity* is quite out of the question.

9. Name the sick clubs, provident and self-supporting dispensaries, in your neighbourhood, and give your opinion of their effects on their members, and on the medical profession.

N.B. A copy of the rules and reports would be very useful to the Committee, and also information on the following points: average per centage of members on sick list; average duration of illness; average pay per case; whether membership is limited within a certain amount of income; and if so, within what amount.

10. Can you give any information regarding the origin of the sick clubs, the provident and self-supporting dispensaries, and the medical charities with which you are connected, or which exist in your neighbourhood?

JOHN ROSE CORMACK, *Chairman*,
THOMAS CHARLES, *Hon. Secretary*.

The sub-committee having been reappointed, (with the addition of Dr. Cormack,) was entrusted with the circulation of the queries, and with ascertaining the best manner of securing funds for the purposes of the Committee.

Mr. Cantrell, of Wirksworth, attended the Committee and communicated much valuable information regarding the sick system. The next meeting is to be held in January.

EDITOR'S LETTER BOX.

CHLOROFORM IN MIDWIFERY.

LETTER FROM J. C. BLOKAM, ESQ., TO THE EDITOR.

SIR,—I am unwilling to enter into a controversy on the subject of anæsthesia in parturition, because, in the first place, engaging in any controversy has a strong tendency to enlist one inseparably on one side or the other of the question, both in regard to reasoning and in regard to practice; and, in the next place, there are probably not many of your readers who will wish to follow the controversy now referred to. Mr. Deane, however, brings his great guns into the field, and opens such a heavy cannonade on my letter published in a late number of the *JOURNAL*, in reply to Dr. Simpson, that I seem to have a claim upon you for another hearing. If Mr. Deane's shots are calculated to make me tremble for my own safety, or to frighten me with a picture of the many faults I have committed, it is incumbent upon me to show that the masonry of my arguments has not been shaken by his heavy artillery.

Mr. Deane apparently considers my letter an able one (and I thank him for his commendation); and, as far as I understand, he has but one objection to make to it, viz., that it is false—not false in any statement of facts, but, in the matter of ratiocination; and it is for me to show—if I can—that the falsity exists merely in his imagination.

In the first place, Mr. Deane, I think, misapprehends the position I assume in the subject under consideration; and I may as well explain what my position is. Mr. Deane seems to assume, and to intimate, that I have not had the benefit of any personal observation of anæsthesia in labour, and he evidently supposes me to be a decided opponent to its use. Now, I think I may say that he has no ground for the assumption; and I can assure him that he is quite wrong in the supposition. Mr. Deane says, in a former letter, "no man ought to utter a word on the question unless he can give the affirmative to the question, 'Have you used chloroform in labour?'" This may be a very convenient doctrine, because it must be nearly tantamount to excluding all but its advocates from the discussion. Those who have not committed themselves, who still wish to be determined in their practice by the results of experience and reason, are to be entirely excluded. I entirely dissent from the doctrine; and I say that I am just as much, and just as little, capable of detecting the errors in reasoning of Dr. Simpson, or of Mr. Deane, if I have never seen a case treated with chloroform, as if I had used it a thousand times. Now, I tell Mr. Deane frankly, that I have not ever used chloroform in labour; but I have heard the sentiment expressed, during the birth of a twelfth child, that it required more courage to be put under the influence of chloroform than to undergo the "agonies" (to use the oft quoted term which Mr. Deane uses) of labour. I have not ever used chloroform in labour; but I have not ever had occasion to declare myself, and never have professed myself, to be an opponent to its use. I believe, however, that I shall not adopt the practice—not in ordinary labours—until my mind is more satisfied than it is at present, that such practice is justifiable, and that it is unattended with danger. The tone of Mr. Deane's letters makes it appear that he does not consider the question as one open to discussion; his mind is determined on the matter, and no more need be said about it—or rather *against* it. It appears to me that the whole merits of the question have not by any means as yet been elicited, and that experience must necessarily, as yet, have a great deal to say upon it. I feel that, being engaged in practice, it is in some measure my duty to study the question; and that it is one, moreover, of considerable interest—its interest and importance taking a much wider range than that of any professional practice. The evidence, at present deducible from experience, I consider to tend strongly to show that the practice is not unattended with danger.

The two cases detailed by Dr. Murphy, in the number of the *JOURNAL* for September 2nd, seem to me to afford strong evidence in this respect. Dr. Murphy argues at some length to show that the chloroform *ought* not to have been the cause of these deaths; but it appears from his own statement that it was so. He shows that women have died unexpectedly after parturition, without chloroform; but he cannot undertake to say that they have so died, with the peculiar symptoms that these cases exhibited. Such deaths, after all, are of very rare occurrence; and it is at least very unlucky for the cause of humanity and chloroform, that two fatal cases

should already be on record, in connexion with the use of chloroform; considering the small scope there has been for them, comparatively. Dr. Murphy says, that it is not to be argued that, because these deaths occurred after the use of chloroform, therefore they must have occurred in consequence of it; but he does not tell us that it would be an unfair inference, that the deaths were occasioned by chloroform under the following circumstances, viz., that they occurred in a very unusual manner—that is, within a short period of the apparently satisfactory completion of labour; that they occurred in connexion with very peculiar symptoms; that these peculiar symptoms were the very ones that are known to attend upon the exhibition of chloroform; that the fatal termination was inexplicable upon any other supposition, than that of the chloroform having occasioned it. In one case, a *post mortem* examination took place, and disease of the kidneys was found, which was quite inadequate for the explanation of the symptoms (including the last fatal one), *independently* of the chloroform; and the lungs were highly congested, which was precisely what was to be looked for as the effect of anæsthesia. We certainly do not *know* that these deaths were occasioned by chloroform; but it is at least highly probable that they were so, and we must often be content to regulate our practice by probabilities. I do not see how the first two fatal cases could well exhibit more conclusive evidence as to their causation: what is wanting to complete it that *could* be found in these cases? Two well authenticated cases, such as these, ought to have considerable weight. The two recorded cases are in all probability not the only ones that have occurred of the same kind; and I cannot understand any person allowing his convictions (I do not say practice) to remain uninfluenced by them. So much for past experience: that which is to come may prove more encouraging. For my own part, I cannot look upon the question as settled; and I still look out for further evidence.

In the next place, I think Mr. Deane appears to have written his letter under the impression that I was arguing the main question—for or against anæsthesia; but all my arguments, I believe, were limited in their application to the remarks made by Dr. Simpson; and this must be kept in mind whilst judging of the appropriateness of the arguments.

Mr. Deane says, that no special pleading can stamp Dr. Simpson's reasonings as fallacious. I am not concerned at all to controvert this position—far from it; but I conclude that I am to understand Mr. Deane as charging me with special pleading, and this I cannot accede to. I only ask any person, who takes an interest in this matter, to read Dr. Simpson's letter, and to read mine; and then say whether Dr. Simpson's line of argument be fallacious or not. Mr. Deane may say, "But read my letter also." By all means; but then read this likewise. I sincerely feel that any special pleading would be peculiarly misplaced in such a matter as this. I was certainly quite unconscious of any special pleading whilst writing my letter; and if it have existence, I must consider it to be a great fault. It is difficult, however, to deal with a general accusation of this kind; and I must, for the present, console myself with the consideration, that it is a very common move with those who are hard pressed by an argument which they feel to be hostile to their own views and principles, to condemn it as a specimen of special pleading.

The line of argument that I directed against Dr. Simpson's analogies was precisely that of showing that they failed in the one essential point; and the distinctions, therefore, referred to in Mr. Deane's third paragraph, are mere surplusage; the paragraph is a mere collection of words, *independently* of the particular instances he may give of my non-observance of these distinctions; the examples forming the body and substance, connected with the dress.

I say this much by way of parrying the *thump* contained in this portion of Mr. Deane's letter. I turn now to the first instance he adduces of my error; and, in doing so, I notice that which I may distinguish as the criticism of this portion.

In Mr. Deane's fourth paragraph, I find the following words, which are to be understood as collected from my ninth paragraph; and the first six words are marked as being an extract. "A fork may aid in eating; but he does not see how chloroform can aid in labour." The sentiment contained in the eleven last words, he attributes to me, but without any ground. When a person makes a quotation from what another has written, for the purpose of criticising it, it is not amiss to be scrupulously attentive to the correctness of the quotation; but Mr. Deane does not subscribe to this maxim, or, at any rate, he disregards it repeatedly. I do not know where Mr. Deane finds the words which he gives as a quotation; they do not occur in my letter.

Neither have I anywhere expressed the sentiment which he attributes to me in the remainder of the sentence. I distinctly disclaim the sentiment as any of mine. I do not know that it can be necessary for me to do more than repeat the passage he refers to in Dr. Simpson's letter, fully and *correctly*, and also that referred to in my own letter: the mere juxta-position of the two passages seems to be all that is needed, to judge of the merits of Mr. Deane's criticism. Dr. Simpson says: "In the reign of the earlier Stuarts, forks were introduced from the continent, to assist our hands in the act or function of seizing and lifting the divided portions of meat, etc., that we wished to eat. But this was a very sad and uncalled for innovation upon the old and established physiological functions of the human fingers; and, at the time, it was as loudly opposed and decried as the modern employment of anaesthetics in aiding the physiological function of human parturition." The passage in my own letter is thus: "The use of forks is alluded to as a means of assisting our hands in lifting portions of meat, etc.; and this innovation is then likened to the employment of anaesthetics in *aiding* the functions of human parturition. But there is no objection made, apparently, to the use of anaesthetics for the purpose of *aiding* parturition, and consequently the two cases are not analogous." I think, if I enter a little more fully into this part of the subject, Mr. Deane himself will see that my argument is sound, and that Dr. Simpson's analogy is unsound. Mr. Deane's criticism rests on the use of the word *aid*—on the use that Dr. Simpson makes of it, and the use that I make of it. The word is apparently an influential one in Dr. Simpson's statement of his own ideas; but Mr. Deane says that it does not form an essential element in his analogy. Now, I maintain, in spite of anything that Mr. Deane has advanced to the contrary, that it is thus essential. What is the essential characteristic of the innovation immediately under consideration—the characteristic that is relied upon as rendering it analogous to the innovation of subjecting women to the influence of chloroform whilst in labour? There are two characteristics for us to choose between; and I apprehend that we must take one of these two as that which is involved in Dr. Simpson's analogy. One of these characteristics is the aid which this and other contrivances and innovations afford towards rendering our bodily organs more efficient tools in the performance of their several natural functions. Our organs are admirably contrived for the general purposes for which they are intended; but they have, none of them, perhaps, that sort of perfection which precludes the possibility of their being rendered by special contrivances more efficient for individual purposes. The other characteristic consists in the substitution of some artificial contrivance for the natural function—the abrogation, suspension, or destruction of the natural actions of the organs; as was done by binding infants in swaddling clothes, or on wooden boards, and tying their heads to their shoulders (these practices were innovations formerly, though they are exploded follies now), in order to prevent the injury that nature would have left them to experience by using their limbs, and which, no doubt, they do now frequently sustain, to a certain extent. I conceive that Dr. Simpson did not mean to refer to this latter characteristic, though it would have been very relevant to have done so, seeing that it involves precisely the objection that the opponents to the use of anaesthetics raise to the practice: it is the characteristic which ought to have been referred to, in order to make good the analogy. I conceive that Dr. Simpson could not have referred to this characteristic, because I do not see that the use of forks deranges, suspends, or impedes any one of the natural functions. The local and partial, the general and vital actions, are all called into exercise, just as much with the use of forks as without them. I conceive that Dr. Simpson is in the position of not only implying that he referred to the former characteristic, by the use he makes of the words "*assist*" and "*aiding*"; but also that he *must* have referred to this. And then the analogy fails, *quoad* the point on which the objection of the opponents rests. I think neither Dr. Simpson nor Mr. Deane can understand accurately the principle on which the objection rests. A large portion of Dr. Simpson's arguments is in many respects parallel to what it would be if he were to insist upon medical men having children bound hand, foot, and head, upon boards, in order to prevent the bruises and injuries (sometimes severe ones) that now arise from the physiological use of their limbs—*because* they (the medical men) bind up limbs and joints to prevent movement, whilst they are in a state of disease.

Having disposed of this first instance of my mistaken analogy, I find there is none other brought under notice, and conclude that the most formidable was selected for exposure.

There are some other remarks in the same paragraph, which concern me only secondarily; they more immediately concern Dr. Simpson and Dr. Meigs. It is a good maxim, and one received in the profession as generally correct, that nature should be assisted and forwarded in her functions and remedies, rather than obstructed or perverted; that she should be allowed to take her own course, rather than be forced into one that may appear to our understandings, fancies, or prejudices, to be better. And this maxim is, in principle, perhaps, always correct; but, in practice, not always applicable: there is often a difficulty in determining what the natural course is, and whether the course actually taken may not be a provoked one, and consequently requiring control. There can be no difficulty of this kind here; there can be no doubt that it is not a provoked action, but the natural action, that is endeavoured to be counteracted by the use of anaesthetics in ordinary parturition. Mr. Deane considers it to be inconsistent for the same party to advocate the control of the perverted action of the disease, and also to object to counteracting the natural state of the system, in parturition; in the same way as Dr. Murphy thinks it *inconsistent* to object to the use of anaesthetics in parturition, and at the same time to use them during surgical operations; but it should be remembered that it is not a natural condition for muscles, nerves, etc., to be severed by the knife; and that the pain attending upon the process is not a natural physiological pain. The controversy, I think, must in great measure be kept up by the one party misunderstanding the position for which the other contends. The opponents of the new practice say, that you cannot interfere with nature in her own course of action, and thwart her in her own plans and intentions, without mischief, or the danger of mischief; and this position is certainly in itself a correct one; and it has a double application. It applies against deranging a course which is a natural one, and it sanctions deranging one which is not natural. To quell the non-natural pain of a surgical operation may very well be a benefit, at the time of the operation, and also subsequently to it; but, in parturition, the circumstances being reversed, the rule, in order to remain the same rule, must be applied inversely. Is it not quite consistent with reason for these opponents to suppose, until experience can be appealed to to decide the point, that there must be danger of seriously deranging the vital energies by such artificial interference with the functions of the nervous system—a system, the whole of which is so essentially involved, both physically and psychically, in the act of parturition?

In discussing the position that the pain of parturition is part of our nature, I think each of the two parties shows an inclination to refer to the parallel position, that the toil of manual labour is part of our nature; each party feeling conscious that the facts and principles of one of these positions, are calculated to illustrate those of the other. Mr. Deane, in his former letter, suggests that this part of our natural condition may be abrogated by the possession of £500 per annum; but he should remember that money is available in this way only so far as it may confer upon the possessor a command over the labour of others; so that for every one relieved from, there must be many subjected to, this burden; and it thus becomes evident that labour must remain the lot of the great mass of mankind. And is this necessity of our nature to be looked upon as an evil? Surely not; it may be a source of temporary suffering, but no doubt of lasting benefit.

I now proceed to Mr. Deane's fifth paragraph. His objection here refers to my using the same words in a wider range of meaning, which Dr. Simpson had used in a more contracted range. But why do I do so? Dr. Meigs prescribes to himself a certain latitude in his endeavours to relieve human suffering. He relieves the suffering arising from a provision of nature—from disease; but he objects to the use of one particular means for relieving the suffering which he considers to be the physiological attendant upon one particular act. Dr. Simpson then argues that if he would do the one thing, he ought to do the other also. The gist of Dr. Simpson's argument (as I understand it), is this; if you are justified in relieving any human suffering, you are bound to relieve all human suffering. This appears to me to be bad reasoning; and in order to put it to the test, I have recourse to Dr. Simpson's method. I apply his principles in a still larger circle than he had in view, following, by this means, the erroneous example that he had set, for the purpose of exposing the error involved. It appears to me evident, considering the tenor of the whole paragraph in question, that this was the line of my argument; and that Mr. Deane's criticism, however learned, is totally uncalled for. I admit that the range of my idea was quite different from that of Dr. Simpson's; but so is Dr. Simp-

son's quite different from that of Dr. Meigs. Dr. Simpson urges Dr. Meigs, on the ground of consistency and humanity, to extend his sphere of action from the relief of morbid pain to the relief of natural physiological pain, which Dr. Meigs thinks cannot be done with impunity. I suggest, in return, that Dr. Simpson should extend his sphere of action from the relief of the pain of disease, and the relief of the pain that naturally attends upon a natural process, to the relief of the pain of a wounded conscience. Dr. Simpson no doubt will not feel himself bound, in consistency or humanity, to do as I suggest; neither will Dr. Meigs feel himself bound to do as Dr. Simpson urges him. The principles of right and wrong are different in each of the three positions, but there is sufficient analogy in the differences.*

I now come to Mr. Deane's sixth paragraph; I am really at a loss to account for the accusations here put forward. I must first give some explanation of what the state of the case is, because I have to show that not only are Mr. Deane's arguments perfectly irrelevant, but, also, that his statements are quite the reverse of correct. Mr. Deane gives the sixth, seventh, and eighth paragraphs in my letter, as his subject. It is the sixth paragraph that is principally concerned. In this paragraph I expressly refer to the twenty-third of Dr. Simpson as forming the subject of my argument. Therefore the sixth paragraph of my letter and the twenty-third of Dr. Simpson's contain the essential matter for determining the merits of this present dispute; both these paragraphs are short ones. Dr. Simpson introduces a sentence, which is placed between inverted commas, for the purpose of expressing in small compass the position which he considers his adversary to occupy, and of propounding the subject of his own argument; and the argument which he erects upon this foundation then, forms the subject of my argument. The sentence alluded to is as follows, "I do not believe that any one in Dublin has, as yet, used a carriage in locomotion; the feeling here is very strong against its use in ordinary progression, and merely to avert the ordinary amount of fatigue which the Almighty has seen fit—and most wisely we cannot doubt—to allot to natural walking; and in this feeling I heartily and entirely concur." I now quote from Mr. Deane's statement (p. 821, par. six, beginning with the word *In*). "Dr. Simpson had argued that the pain and extreme fatigue caused by the last few miles of a journey of thirty miles on foot, have a strong resemblance to the last stage of labour". Dr. Simpson *had done* no such thing. I shall not be accused, perhaps, of supererogating nor even of special pleading if I show what he *did do*. Dr. Simpson, seven columns further on in his letter, whilst writing under a different text, uses words which it is pretty evident must be those referred to by Mr. Deane, though I admit they are *very far* from being identical; they are, at all events, the only ones I have been able to find bearing any resemblance. This part of Dr. Simpson's letter is, in its turn, dealt with in mine, on its own merits; and is not involved in Dr. Simpson's twenty-third paragraph, and still less is it in my sixth. A few lines farther on, Mr. Deane says, "the words 'ordinary fatigue of walking', are substituted for the words 'a continuous journey of thirty miles on foot'". I emphatically deny the fact of any such substitution. Why, speaking in a logical sense, I need never have seen these words of Dr. Simpson's when I wrote mine—the two sets of words are not only perfectly distinct, as to their location, but they refer to two distinct branches of the general subject. The passage from which Mr. Deane takes these words, is to be found in my sixth paragraph; the passage is as follows, "it certainly is unwise to renounce the ordinary amount of fatigue that attends upon ordinary progression and natural walking". And now, having shown what these words do *not* refer to, I will explain what they *have* reference to. I have used these precise terms because, by so doing, the terms as well as my meaning are strictly in accordance with those of Dr. Simpson, to which they relate, as will be made evident by a reference to the passage I have already given from his twenty-third paragraph. I cannot find the half page in my letter that is devoted to prove that the ordinary amount of fatigue that attends upon ordinary progression is conducive to health; but I do find *six lines* devoted to such a statement in regard to "ordinary progression and natural walking".

Mr. Deane's thumps in this part of his letter are particularly heavy; and I say that his statements are erroneous, his accusations are unjust, and his arguments are perfectly inapplicable to the occasion.

In referring to Mr. Deane's seventh paragraph, which relates

* My fourth paragraph, which Dr. Deane calls the third, refers to the eighteenth of Dr. Simpson's—not the fourteenth, as it is printed in my letter.

to my eleventh and twelfth, I must observe that there is a misprint in the twelfth. I am not sure what the correction should be, but I believe that in the third line, the words, *the proposition is*, should be inserted before the word "that". Mr. Deane remarks, "The reasoning is good, except that, unfortunately, it is all based on the assumption that anaesthesia adds to the danger of labour". In the eleventh paragraph there is no reference whatever made to the danger attendant upon anaesthesia. I allude to the dangers of railway travelling, and the dangers of parturition; but I allude neither directly nor indirectly to the dangers of anaesthesia.

In the twelfth paragraph, I do allude to the dangers of anaesthesia, but there is no such assumption as Mr. Deane speaks of. I assume nothing of the kind. Dr. Simpson takes up the suggestion that there is such additional danger (see the heading to this part of Dr. Simpson's letter which is marked 4, and which stands just above the paragraph to which my remarks refer, viz.: par. thirty-three), and then argues upon the hypothesis. My argument involves merely the hypothesis which Dr. Simpson brings under consideration. Mr. Deane might as well, or rather better, accuse Dr. Simpson of making this assumption, as to accuse me of it.

To Mr. Deane's last paragraph I will only observe,—to what strange resorts are men reduced, who dispute in favour of innovations, instead of attempting to test (I do not mean use) them.

I am, etc.,

JOHN C. BLOXAM.

Newport, Isle of Wight, Sept. 22nd, 1853.

CHLOROFORM IN MIDWIFERY.

LETTER FROM ROBERT MANNERS MANN, ESQ., TO THE EDITOR.

SIR,—I am much pleased to find on reading your remarks on chloroform in our JOURNAL, for Nov. 4th, that you still hold the opinion that no death from its exhibition in midwifery has occurred. If such be the fact (and from what little experience I have had, and from what I have carefully read on the subject, I am inclined to believe it is), it must be highly gratifying to all accoucheurs who are inclined to mitigate the agonising pains of labour.

In all cases where I have administered it, not only have I been satisfied with its anæsthetic effects, but my patients have expressed themselves as wonderfully relieved, and that, if possible, they would never be confined again without it. With regard to the dose, I have followed Dr. Snow's advice, and given from fifteen to twenty minims, always cautiously, and taking care to allow the occasional admixture of air. I have seldom found it necessary to deprive my patients of consciousness; but whenever rambling or incoherent talking has taken place, I have immediately removed the chloroform, and I believe that the patient was then almost, if not completely, free from pain during the expulsive efforts of the uterus.

I have rarely administered altogether more than from half an ounce to an ounce, never commencing till the os uteri is tolerably dilated, from the size of a crown piece upwards. But, in one instance, a first labour, where the pains or rather the contractions were very powerful and protracted for several hours, in a fine, stout, young woman from the country, I administered as much as three ounces and a half, or more, certainly not less; and in this case I regulated it according to the patient's sensation of a freedom from pain; i.e., the moment she felt pain after the removal of the anæsthetic, she called out hastily for more; and when once sufficiently under its influence, I found that, as Dr. Snow tells us, she could go through several strong and effective uterine contractions without a fresh application.

I believe I have observed labour to a certain extent retarded by it, but not materially; and if so, the patient in the meantime suffers little or no pain. Again, in other cases, it has undoubtedly assisted in dilating the perineum and os uteri, and has even accelerated the muscular contractions. I do not think it should be given indiscriminately; but, in those where the pains are lingering, severe, and protracted, as also where there is a rigid os uteri, and in instrumental or operative cases, I deem it invaluable. In conclusion, allow me to remark that my humble opinion entirely coincides with yours, viz.: "that the cautious inhalation of the vapour of chloroform, during labour, is entirely free from danger, and calculated to afford merciful relief from pain in one of the most agonising trials of humanity."

I am, etc., ROBERT MANNERS MANN,
Late Surgeon to the Manchester and Salford
Lying-in-Hospital, etc.

2, Great Bridgewater Street, Manchester, Nov. 5th, 1853.

CHLOROFORM IN MIDWIFERY.

LETTER FROM W. SANKEY, ESQ., TO THE EDITOR.

SIR,—The discussions that have lately appeared in the ASSOCIATION JOURNAL on the subject of chloroform induce me to furnish you with the results of my experience of this valuable agent in midwifery, surgery, and other cases. It is now upwards of five years since I began to employ it in labours, and although, from the prejudice of patients, and much more frequently of relatives or nurses, I have not used it in the majority of cases till lately, yet I have had opportunity of testing its efficacy in every variety of labour. Its efficacy in first labours, in producing relaxation of the os uteri and external parts, with copious secretion of glairy mucus, has been most marked. In every species of labour, it soothes the patient, and materially lessens her sufferings, in small doses, and entirely renders her unconscious when administered to the full extent.

The only preternatural case of consequence was a shoulder-presentation. Turning was effected with considerable difficulty, but no expression of pain escaped the patient, except a slight groan; and, when she became conscious, she would not believe that the child was born. I may add, that, in alleviating severe after pains, chloroform has been most useful.

The last case was a lady who, from religious scruples, had objected to the use of chloroform in two former labours; in her third, which took place on the 4th instant, she was kept under the full influence for two hours, and did not wake up till some time after the removal of the placenta.

It is, I presume, unnecessary to give the details of all the cases, particularly as I am able to state that, in no single instance, has the patient suffered the slightest inconvenience from its use. In surgery, I have found it most useful in hernia and dislocations, as well as operations. Among other instances of the value of this anæsthetic agent, I may mention the passage of a renal calculus where, from irritability of stomach, every anodyne was instantly rejected; and most severe dysmenorrhœa in several instances, that had equally resisted the usual remedies.

I fear I have been too prolix, but you will abbreviate where you deem proper.

I am, etc., W. SANKEY.

Dover, October 9th, 1853.

THE VACCINATION ACT.

LETTER TO THE EDITOR.

SIR,—I have seen with much concern and some amusement the numerous angry communications which have lately appeared in the JOURNAL on the subject of the New Vaccination Act. It was inevitable that the operation of the act should excite hostility somewhere. *Summum jus, summa est malitia*.

But surely the legislature must observe with chagrin and astonishment the conduct of its medical assailants. Their untimely valour, their awkward tactics, and their false position, seem better calculated to provoke derision than to procure redress.

In what troublous times do we live! The peace of Europe is imperilled by the arrogant ambition of the Czar; the repose of the medical profession by the "flagrant impositions" of the New Vaccination Act. The Emperor of all the Russias seeks, it is said, to *Burke* the rights of his sublime and turbaned brother; the British legislature, it is affirmed, has abrogated those of our ill used profession. *Bella, teterrima bella*. War in the East, war in the West.

But let me ask, Have the medical malcontents, the promoters of this *bellum sine hoste*, well considered the formidable character, unlimited resources, and favourable position of the foe? Have they duly estimated their own inferiority in strength, position, and weight of metal, as well as the extent of treachery in their camp? Surely the result of so unequal a contest is not difficult to predict. It is earnestly to be deprecated, as *occurring between recent allies*. Let hostilities be suspended; let a truce be proclaimed. The interchange of a few "notes" may conduce to a "pacific solution".

Now let us take counsel together. How in reality stands the matter? A large majority of the profession called for a compulsory vaccination act. They furnished the materials and the arguments for the measure. The legislature—*erectis auribus, intentique ora tenebant*—were convinced, and promptly complied. In framing the measure, that august body felt assured of the disinterestedness of the profession, and confidently relied on their proverbial devotion to the public good. They duly appreciated the parsimony of the public in all sanitary matters,

and were keenly alive to the power of the rate-payers at certain seasons. With a view, also, to reconcile the community to a measure which, by captious or careless observers, might be deemed arbitrary and offensive, or cunningly devised for the special benefit of the medical profession, they took unwonted pains so to frame it that high and low, rich and poor, the subjects and the agents of vaccination, should equally feel and unanimously acknowledge their mutual participation in one grand and comprehensive scheme of social sacrifice for social good.

The bill passed. It was thus decreed by Act of Parliament, that pecuniary interests, private feelings, and popular prejudices, in reference to vaccination, should share the same fate, and yield to the public welfare.

Whether the act will accomplish the beneficent and impartial designs of the legislature, time alone can tell. It is quite possible that parliamentary wisdom may prove inferior to parliamentary power, as many "an act to amend an act" amply testifies. Present appearances, indeed, are rather unpromising. If the educated and intelligent members of a liberal profession already manifest symptoms of rebellion; if the abettors of compulsory vaccination are the foremost to exhibit examples of contumacy, on the score of self-interest,—what are we to expect from the poor and the ignorant, when their feelings and prejudices are assailed?

Come, come, gentlemen; this will not do! *Sævitique animus ignobile vulgus*. If we conceive ourselves aggrieved, let us make our complaints known in the right quarter, and in a becoming manner. Remember, "till the law is amended, it must be minded." Let us be reasonable and consistent. "What is sauce for the goose is sauce for the gander." Instead of vain and empty threats, never likely to be executed with impunity, and rude and ungentelemanly conduct to one of the involuntary administrators of part of the act—to whom the profession is deeply indebted—let us behave like men of sense, and appeal as once to the author, promoter, and approver of the measure, viz., Lord Lyttelton, Sir John Pakington, and Lord Palmerston. Let us boldly and candidly declare to them, that, in urging them to annihilate by Act of Parliament vulgar prejudices, mawkish feelings, and ignorant objections to vaccination, we had not the remotest idea that we also should be subjected to such grievous "impositions" as the act contains; that we cannot see any necessity for it, but deem such treatment as a strange way of "backing your friends"; that they may rest assured the act will prove a dead failure, unless these preposterous and arbitrary "impositions" are removed.

Lord Palmerston, who invites information and suggestions from all quarters, will be too happy in receiving ours. I doubt not he is already expecting them; for he knows the act will not work. Lord Lyttelton and Sir J. Pakington have expressed their desire to render the act agreeable to the profession. Union, they say, is strength. That is all nonsense in parliamentary acceptance. In Parliament, numbers alone prevail. If otherwise, union would be unattainable with us. Let every individual medical malcontent, therefore, after addressing the above named personages to the effect suggested, if they please, make known his complaints to his own parliamentary representative also, and claim his attention. Such a course, I flatter myself, is far better calculated to obtain redress than the random and reprehensible proceedings which I have ventured to condemn. It is possible, I grant, that some monopolising public vaccinators may forward counter memorials and remonstrances, expressive of their unqualified satisfaction with the act, and of its pleasant operation in their neighbourhood; but the obliquity of their judgment and the transparency of their motives will be too obvious to the wisdom, and their numbers and influence too insignificant for the power, of Parliament.

I trust, sir, if you cannot altogether approve my plan, you will at least allow me to commend it, as I now do in all humility, to the careful and candid consideration of my disappointed and indignant brethren.

I am, etc.,

BUBRICOLA.

Nov. 5th, 1853.

WHAT CAN THE ASSOCIATION DO FOR MEDICAL PUPILS?

LETTER TO THE EDITOR.

SIR,—I am one of a class usually described as *immoral and depraved*—medical students; and certainly with some reason. Although the causes of this immorality have frequently been laid before the public, and are patent and well known, nothing has been done to meet the wants of that numerous and increasing body. An effectual remedy for this depraved

proposed, and carried out in one establishment. I mean the collegiate system. The cost of education at the Queen's College, Birmingham, is more than the majority of students could afford: for that, this system would be perfectly effectual.

But, can nothing be done in other ways? It is proverbially true that "no man careth for the student of medicine". If he have the advantage, during his apprenticeship, of being received into the house of his master, and having constant supervision exercised over him; when he attends lectures and walks the hospitals, all restraint is removed. His principles, as yet, perhaps, only the force of habit, are sorely tried; and with the many temptations which surround him (and which I need not stop to mention, as they must be well known to every medical man), can we wonder if he fall?

Youth is the most ductile period of life: and it is precisely at this period that the medical student is left to himself. I should not say left to himself: far worse, he is associated with youths of his own standing, who laugh at his religious scruples; and, in his attendance at the hospitals, he must necessarily meet with those abandoned females who are ever ready to corrupt him. The surgeons of the hospital (with some praiseworthy exceptions), do not watch over his conduct; indeed, it would be in general impossible for them so to do. The chaplain of the hospital has no authority or influence over him.

What, then (laying aside the system mentioned above as in most cases impracticable), can be done? Can the Association do nothing?

The Pharmaceutical Society have organised a body of "associates", consisting of apprentices to the members. These associates, by paying an annual subscription of 10s. 6d., have the monthly journal, and are admitted to other privileges; and this single bond of association has contributed greatly to the respectability of the youths.

Though the present race of medical students have no connexion probably with the Provincial Association, yet, if a proposal were made to them, admitting them on payment of a small subscription to various privileges, as might seem fit, I think many would avail themselves of it. And if the apprentices of members be induced to join in it, they will, when their diplomas have been obtained, become members of the Association, and so greatly conduce to its stability.

We are constantly told that it is to the rising generation, that society looks for great benefits. Let society take up the cause of the medical student and apprentice, and assuredly she will receive a full reward.

There is no profession on earth in which more deference is paid by the juniors to the seniors than the medical, and if some of our leading men were to interest themselves in this cause, I am persuaded that much, very much good might be effected.

The thanks of many students will be justly due to you should you insert these remarks. Discussion may be elicited. "Where there is a will there is a way"—in most cases.

I am, etc., A MEDICAL STUDENT.

October 10th, 1853.

MR. HUNT'S PAPER ON DIARRHŒA.

LETTER FROM JOHN GROVE, Esq., TO THE EDITOR.

SIR,—It is with some hesitation I venture to make a few comments on Mr. Hunt's contribution to the JOURNAL of the 28th October. His first paragraph contains an erroneous assumption, an unsubstantiated charge, and a claim of jurisdiction. With your permission, I will endeavour to rebut the assumption, to repel the charge, and to dislodge the claim.

The first nine words, "The frequency with which diarrhœa degenerates into malignant cholera", constitute an assumption from which, I believe, a very large proportion of the profession would withhold their assent. Now, as this is the whole theme of Mr. Hunt's paper, it requires but little argument to demonstrate the utter uselessness of applying "first principles" to the unproved dogma, "the degeneration of diarrhœa into malignant cholera". Can Mr. Hunt, or any one else, draw the line which divides cholera and diarrhœa? Is there more difference between these two diseases than between simple and malignant scarlatina? The real question for solution is, whether cholera and epidemic diarrhœa are essentially two distinct diseases, or are grades of one malady having a common cause. It is my humble opinion, that until this point is settled, no discussions on treatment, however temperate and considerate they may be, can lead to any practical results. Indeed, it was the very failure of success from the application of the first principles of medicine which led every man to seek his own line of treatment out of the beaten track of ordinary practice. Hosts of men, to

whom orthodox physic is an immutable creed, have found their physiology and pathology, however perfectly attained, serve them but little in the face of the deadly foe. What wonder then that men, earnest and zealous in their calling, put forward their views in the public journals of the day. And here I would refer to the unsubstantiated charge.

Mr. Hunt talks of the "zealous scribblers in our periodicals", and he has not much respect for "their somewhat dogmatic and earnest style". As to the epithet, "scribblers", the charge falls rather on the editors of journals than on the writers of the offending documents; for the former have a discretionary power in the selection or exclusion of articles.

The onus of defence, on this head, rests manifestly with the journalists who have admitted so much "scribbling" into their periodicals; but it is not my business to attempt their vindication.

Mr. Hunt further writes, for "incompetent" and "indiscreet" practitioners and others equally censurable, who, he assumes, are very numerous, and incapable of exercising their calling with judgment or discretion, simply because with much zeal and energy they have carried out and advocated a definite line of treatment for a specific disease, not for *all cases* of diarrhœa, but for all such as range themselves within the epidemic cause.

Mr. Hunt, in the conclusion of his first paragraph, takes upon himself the generalship of the nomadic tribes of empirics, who have, as he thinks, wandered from the paths of legitimate physic; he, however, allows that some of them are respectable, which may in some measure account for his having taken upon himself such responsible duties. Now, I really do not think that the "zealous scribblers" are likely to acknowledge their general; if they are deserters, they will remain deserters still; if they are honest searchers after truth, first principles based on anatomy, physiology, and pathology, I can without hesitation affirm, are as much a guide to them as Mr. Hunt. His claim to generalship is, I think, with all deference, as much a dogma as any he has himself condemned. If there have been over zealous writers, they have had an exciting theme.

I have the greatest respect for zeal and energy wherever they are to be found; but in such a cause as that of saving human lives, those who exhibit these qualities are entitled to the respect of all persons. If there has been evidence of vanity, weakness, or folly, ignorance or obstinacy, in the condemned writings, we must remember that the wheat cannot grow without the chaff, and that truth is often reached through a multiplicity of errors. It behoves us to be thankful for what we have, and for what we know: and I think it would always be wiser if we could be contented to let our own lights shine without endeavouring to extinguish those of our fellow labourers.

I am, etc., JOHN GROVE.

Wandsworth, October 31st, 1853.

ARE ARREST OF DEVELOPMENT, MONSTROSITIES, ETC., ATTRIBUTABLE TO MENTAL EMOTIONS OF THE MOTHER?

LETTER FROM G. E. NICHOLAS, Esq., TO THE EDITOR.

SIR,—I have heard so many cases on this interesting subject related, and have witnessed one in particular, from which fair inference might be drawn that arrests of development, blemishes, etc., have been occasionally the result of mental emotion, that, on perusing your remarks on the case reported (in the *American Journal of Medical Science* for April) by Dr. Storrer, I was surprised to find that you discard such an idea, as emanating only from the credulity of womankind.

Dr. Storrer's case seems matter of fact enough. A lady in early pregnancy is much affected at seeing a hen injured—its leg broken by a boy having thrown a stone at it—her mind, continually dwelling upon the subject throughout pregnancy, has become impressed with the idea that her offspring would be deformed; and so it happens, her child presenting at birth arrest of development of one of the lower extremities. Upon this case you observe, "We really do not see anything remarkable in all this; for women are constantly fancying that they are to give birth to monsters, and also insisting on minutely inspecting what is born, when there is no blemish of any kind discoverable upon their offspring." Proceeding, you say, "The discussion on Dr. Storrer's case was very appropriately closed by Dr. Gould mentioning a 'set off' case." "He had lately attended a woman who at the birth of her child was very anxious that its palate should be examined, she having been very unpleasantly affected in early pregnancy at seeing a person

with a very disagreeable countenance from deformity of the palate; notwithstanding her strong apprehension, no effects were visible on the child."

Allow me to relate a parallel case to Dr. Storrer's, but a more forcible one. Mrs. E., in early pregnancy, was very much frightened by a beggar, who solicited alms, holding up to her horrified gaze (I presume with a view of creating pity) the stump of his arm, which had been amputated. Her mind continually recurred with fear to the subject. Her child was born with one arm presenting the exact appearance of having been amputated; the stump being so like (when I saw it, about twelve months ago, the lad being fourteen years old), that many a surgeon might be mistaken as to its nature. Here there was something very like cause and effect. Supposing that another lady in the same condition as Mrs. E. had seen and been similarly affected by the same object without the same result having occurred, surely it would be illogical to call the latter a "set-off" case (by which, I presume, is meant equally good evidence) against the former; to say nothing of the probability of the different result being due to the difference of temperament, sensibility, subsequent occupation of mind to the exclusion of the fearful idea, and of all those collateral circumstances which must of necessity happen in two individuals. Like the latter supposed case, Dr. Gould's (which is in exact accordance with your remarks) can, I think, be considered as negative evidence only, and not referable to that *argumentum ad judicium*, so necessary to a clear investigation. A positive statement is worth a hundred negative ones.

I have ventured upon this communication, in the hope that it may elicit from your numerous readers some well authenticated facts, which may throw light upon this interesting and generally considered inexplicable subject.

I am, etc., G. E. NICHOLAS.

3, Union Place, Clapham Rise, October 24th, 1853.

DR. JUNOD'S HÆMOSPASTIC APPARATUS.

LETTER FROM T. JUNOD, M.D., TO THE EDITOR.

SIR,—I am much gratified by the notice taken in the ASSOCIATION JOURNAL for July 15 and November 11 of my *appareil hæmospastique*. Allow me more particularly to direct attention to its utility in cholera, which I believe I have proved by experiments performed in the Parisian hospitals and elsewhere.

Subjoined are reports of some cases which have come under my notice, extracted from an essay which I published in 1849, in the *Revue Médicale*, entitled *l'Emploi de la Méthode Hæmospastique dans le Traitement du Choléra Epidémique*. It is, I think, especially applicable in the consecutive febrile reaction of cholera; but it has proved useful even in the cold stage.

CASE I. A young woman, aged 22, was received into the Hôpital de la Charité on June 22nd, 1848. During the reaction that followed the state of collapse, she was affected with various cerebral symptoms, which led to a state of coma, despite of all the means which were employed during two days for their removal. The hæmospastic apparatus having been applied during thirty-five minutes, the cerebral congestion was dissipated.

CASE II. A woman, aged 28, having been struck by the epidemic, was received into the Hôtel Dieu on July 2nd, 1842. As in the preceding case, grave cerebral disorder attended the reaction, but it yielded with the same facility, by the employment of the apparatus, except that it was necessary to resort to its use several times during the four following days, in order to remove the cephalalgia and coma.

CASE III. Madame X., aged 70, had a severe attack of cholera. On the tenth day, she fell into a state of deep coma, which resisted the application of leeches to the temples, cold lotions to the head, and sinapisms to the lower extremities. It was determined to employ the hæmospastic apparatus, which was accordingly done at 8 p.m. At 9 o'clock, the expression of the countenance was much improved, the respiration was more free, and the patient began to be able to answer questions. The application was continued for some hours, with steady improvement in the symptoms; when the medical attendants had the patient placed in the warm bath. When she was taken out, there was violent determination of blood to the head, the face became contracted and flushed, the respiration stertorous, the forehead burning; and the pulsations increased by 30 each minute. The patient was unable to answer questions, and fell into a state of profound coma. The apparatus was at once re-applied, and the patient was roused from her lethargy; but she had become too feeble; expectoration could not be reestablished; and she died.

The death in this case, was, I believe, due to the untimely employment of the warm bath.

My object in bringing the apparatus under your notice is that it may receive a trial in cases of cholera occurring in this kingdom. I do not vaunt it as an infallible remedy; but I wish it to be tried impartially, and adopted or rejected on its own merits.

I am, etc.,

T. JUNOD.

86, Cardington Street, Hampstead Road, November 7th, 1853.

HOT WATER CUSHIONS IN CHOLERA.

LETTER FROM MR. W. HOOPER TO THE EDITOR.

SIR,—Since I introduced the elastic water cushions and mattresses for bedsores, etc., I have also manufactured an India-rubber cloth cushion, that resists the action of heat, to any degree up to 212° Fah., and which (when applied as hot as can be borne), in lumbago, cramp, and rheumatism, pain in the loins, stomach, and bowels, generally gives almost immediate relief, and affords the greatest comfort. In obstinate cases of fever, that resist diaphoretics, perspiration may be quickly produced by placing one over the stomach and abdomen. For ordinary application of heat, it is said to be the best means known, while all wetting the bedding, etc., is prevented.

My present object in drawing the attention of the profession to the subject of temperature, is with the view of trying the value of heat in cholera.

It is well known that sudden lowering of the temperature to a certain degree results in death; and it is known that in cases of cholera, as well as poisoning in general, there is a remarkable lowering of the temperature.

I shall therefore be happy to send one of these hot water cushions, free of expense, to any hospital, for the medical officers to report upon.

I am, etc.,

WILLIAM HOOPER.

Pall Mall East, October 25th, 1853.

[The hot water cushion is an admirable means of applying external warmth in cholera. EDITOR.]

NEWS AND TOPICS OF THE DAY.

THE PRESBYTERY OF EDINBURGH AND THE CHOLERA. The Moderator of the Edinburgh Presbytery of the Church of Scotland addressed Lord Palmerston a few days ago, stating that the Presbytery had in view the propriety of appointing, on ecclesiastical authority, a day for prayer and humiliation, within its bounds, on account of the reappearance of Asiatic cholera in this country. Considering, however, that it was likely that a national fast would be appointed on royal authority, they begged respectfully to ask whether such an appointment was in contemplation. The following letter from the Home Office, in reply, was read at the last monthly meeting of the Presbytery:—

"Whitehall, October 19th.

"SIR,—I am directed by Viscount Palmerston to acknowledge the receipt of your letter of the 15th instant, requesting, on the behalf of the Presbytery of Edinburgh, to be informed whether it is proposed to appoint a day of national fast on account of the visitation of the cholera, and to state that there can be no doubt that manifestations of humble resignation to the Divine Will and sincere acknowledgments of human unworthiness are never more appropriate than when it has pleased Providence to afflict mankind with some severe visitation; but it does not appear to Lord Palmerston that a national fast would be suitable to the circumstances of the present moment.

"The Maker of the Universe has established certain laws of nature for the planet in which we live, and the weal or woe of mankind depends upon the observance or the neglect of those laws. One of those laws connects health with the absence of those gaseous exhalations which proceed from overcrowded human beings, or from decomposed substances, whether animal or vegetable; and these same laws render sickness the almost inevitable consequence of exposure to those noxious influences. But it has, at the same time, pleased Providence to place it within the power of man to make such arrangements as will prevent or disperse such exhalations so as to render them harmless, and it is the duty of man to attend to those laws of nature, and to exert the faculties which Providence has thus given to man for his own welfare.

"The recent visitation of cholera, which has for the moment

been mercifully checked, is an awful warning given to the people of this realm that they have too much neglected their duty in this respect, and that those persons with whom it rested to purify towns and cities and to prevent or to remove the causes of disease, have not been sufficiently active in regard to such matters. Lord Palmerston would, therefore, suggest that the best course which the people of this country can pursue to deserve that the further progress of the cholera should be stayed, will be to employ the interval that will elapse between the present time and the beginning of next spring in planning and executing measures by which those portions of their towns and cities which are inhabited by the poorest classes, and which, from the nature of things, must most need purification and improvement, may be freed from those causes and sources of contagion which, if allowed to remain, will infallibly breed pestilence and be fruitful in death, in spite of all the prayers and fastings of an united but inactive nation. When man has done his utmost for his own safety, then is the time to invoke the blessing of heaven to give effect to his exertions.

"I am, sir, your obedient servant,

"HENRY FITZROY.

"To the REV. W. H. GRAY, Moderator of
the Presbytery of Edinburgh."

On the reading of the letter,

The Rev. Dr. CLARK expressed his total dissent from the sentiments expressed in the letter, and said he would not wish to be a sharer in the responsibility of those who refused or declined to give Her Majesty's subjects an opportunity of meeting for prayer in regard to so fearful a visitation.

The Rev. Dr. MUIR said, he thought there could be but one unmingled feeling of pity entertained by them that such a document should emanate from a professedly Christian Government.

Several members expressed concurrence in these sentiments. It was agreed to refer the appointment of a day of humiliation and prayer to the approaching meeting of the provincial Synod of Lothian and Tweeddale, that the same day might be fixed for the whole Synod. The question was put whether the answer of Mr. Fitzroy should be engrossed in the minutes, and it was unanimously carried in the negative.

SUPPRESSION OF THE TRAFFIC IN INTOXICATING LIQUORS. A public meeting was lately held in the Manchester Corn Exchange, to inaugurate the United Kingdom Alliance, established for the suppression, by legislative enactment, of all traffic in intoxicating drinks. Among the leading advocates of the movement present, were—Sir Walter C. Trevelyan, Bart. (who presided), Mr. James Silk Buckingham, Dr. F. R. Lees, the Rev. Jabez Burns, D.D., London; Messrs. Benjamin Parsons, of Ebbiley; Lawrence Panting, M.A., Chebsey; Fergus Ferguson, B.A., Glasgow; Henry Gale, B.C.L., West Lambrook; D. M'Rae; Samuel Bowley; and W. Willis, of Luton. Mr. Pope, the secretary, read a declaration agreed to by a conference of the gentlemen present, previously held at the Athenæum, setting forth the principles on which the Alliance was formed—a declaration in substance similar to that on which the Maine liquor law movement in the United States of America is carried forward. He also read the resolutions agreed to at the conference, recommending the appointment of lecturers and agents, publication of tracts and addresses, etc., in furtherance of the movement. One resolution pledged the council to aid the executive in raising a fund of £2,000, to defray the expenses of the first year's agitation; and, in reference to this, Mr. Pope stated that a subscription was opened at the conference, which had already reached £847:12:6, so that £2,000 was not necessarily the whole amount that would be raised. (Cheers.) Dr. Lees, of Leeds, moved the first resolution:—"That the prime end of social legislation is to secure the utmost protection to the citizens against all destructive acts and demoralising agencies in the commonwealth." The resolution was seconded by Mr. J. S. Buckingham, supported by the Rev. L. Panting, and carried unanimously. The Rev. Benjamin Parsons moved—"That the traffic in intoxicating liquors as beverages is always and inevitably productive of immense injury to the social, moral, and material interests of the nation." Mr. Willis seconded the motion, which was supported by the Rev. H. Gale, and agreed to. It was further resolved:—"That this meeting, regarding the liquor-vending establishments of this country as a source of temptation and a nursery of crime, incompatible with the advance of society in the path of true civilisation, calls for the entire suppression of the traffic in intoxicating liquors. That this meeting cordially approves the objects and constitution of

the United Kingdom Alliance for procuring the legislative prohibition of the traffic in intoxicating beverages, and accords to that movement its hearty sanction and support."

MEDICAL SOCIETY OF LONDON. The following papers are announced as intended to be read at the ordinary meetings of this society.

Saturday, November 12th. R. H. Semple, M.D., "On the Pathology and Treatment of Cerebral Diseases."

Monday, November 14th, in the Physiological Section. Edwards Crisp, M.D., "On the Form and Weight of the Heart, the Diameter of the Aorta, and the Size of the Blood-Corpuscles, in the various classes of Vertebrate Animals."

HUMANITY AND LIBERALITY! The Board of Guardians of the Bakewell Union (Derbyshire), in advertising for a "medical officer" for the "Hartington Middle Quarter District" of the union, makes the following *liberal* offer in this courteous manner:—"The salary of the *person* elected will be £18 per annum." For this large sum he is "to supply such requisite medicines and appliances" as may be required by the poor of the district! To the person who accepts this stipend, the appointment of vaccinator at 6d. each case would of course be a boon.

RETIREMENT OF LOUIS. Louis, the eminent physician of the Hôtel Dieu of Paris, has resigned his appointment, and is about to leave Paris. He is to accompany an invalid only son to the south.

MEDICAL BENEVOLENT COLLEGE. The builder's contract for this national undertaking was signed on Monday by the Treasurer, John Propert, Esq., on behalf of the Council, and the works are now rapidly progressing.

UNIVERSITY OF ST. ANDREW'S:—PASS LIST. The following gentlemen had the degree of Doctor of Medicine conferred upon them on October 21st, 1853:—Henry Bickersteth, F.R.C.S., Cape Town, Cape of Good Hope; Henry Critchley Brodick, L.A.C., Macclesfield; John James Douglas Burns, M.R.C.S.Ed., R. N., Woolwich; John M. Butler, M.R.C.S., L.A.C., Woolwich; Thomay Spry Byass, M.R.C.S., Sussex; Robert Cartwright, M.R.C.S., Salop; Thomas Fernandez Clarke, M.R.C.S., L.A.C., London; Matthew Corner, M.R.C.S., L.A.C., London; James Joseph Cregeen, M.R.C.S., L.A.C., Deptford; George Hickie Daly, M.R.C.S., H.E.I.C.S., Bengal; John Ross Diamond, M.R.C.S., L.A.C., London; Theodore Duka, M.R.C.S., East Indies; Henry James Franks, M.R.C.S., L.A.C., Leamington, Warwickshire; Robert Greenhalgh, M.R.C.S., London; George Arthur Humble, Lic. Fac. Phys. and Surg., Glasgow, L.A.C., Islington; John Matthews, L.A.C., London; John Muir, Lic. Fac. Phys. and Surg. Glasgow, Welwyn, Herts; Lewis Paine, M.R.C.S., L.A.C., London; John Blakemore Phipps, M.R.C.S., Suffolk; Theobald Ringer, M.R.C.S., L.A.C., Clifton, Bristol; E. Malcolm Sinclair, M.R.C.S., Manchester; William Stillman, M.R.C.S., L.A.C., Birmingham; Robert Crossing Thorpe, M.R.C.S., Devon; John Trull, L.A.C., Bath; Arthur Umphelby, M.R.C.S., H.E.I.C.S., Madras; William Webb, M.R.C.S., L.A.C., Barton-under-Needwood, Staffordshire; William Robert Woodman, M.R.C.S., Exeter.

MARISCHAL COLLEGE AND UNIVERSITY, ABERDEEN:—PASS LIST. On October 20th, medical degrees were conferred on the following candidates, after the usual examinations, viz.:

DOCTOR OF MEDICINE. James Valentine Brown, Professor in Queen's College, Galway; William Lindsey Emmerson, Northumberland; Samuel Palmer Goddard, Staffordshire; George Ireland Russell, Kent; Courtland Skinner Shaw, Cheltenham; John Henry Walker, Kent.

BACHELOR OF MEDICINE. Pierre Eloy Bachelet, London; Charles William Whitby, Devonshire.

At the same time, the degree of Doctor of Medicine was conferred on William Stewart, M.B., Mull, Argyleshire; and the following were declared to have undergone and passed part of their examinations for medical degrees:—John Charles Campbell, Aberdeen; Wm. Milne Troupe, Aberdeen.

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London: or to the office of the Journal. Letters requiring immediate attention and revised proofs ought invariably to be sent to Putney.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XLVI.

LONDON: FRIDAY EVENING, NOVEMBER 18, 1853.

NEW SERIES.

THE INVESTIGATION OF CHOLERA.

THE question must often be asked by each of us, "In what way can we as individuals, or collectively, as societies, or associations, or corporations, make the best use of our coming experience in CHOLERA to increase our knowledge of the laws of the disease, and thus to prevent or cure it in future?" Speaking generally, there is but one way to the discovery of truth, and that is by accuracy of observation, judicious experiment, and sound reasoning on the facts so observed and tried. No imperfect observations of individual cases, or any number of statistical tables founded on imperfect facts, can lead to the discovery of the knowledge of the causes of the disease, or rules for right treatment. In the first instance, then, accuracy of observation and close attentive reflection are essentials in any plan. But it is also necessary to clear the mind of its ignorance, and to know exactly what is really known. One of the commonest causes of failure, is taking for granted that we are wise, when, in truth, we are ignorant. In a probable and progressive science like medicine, where laws may be laid down on paper with dogmatic authority, and are often incapable of contradiction unless by a long and careful inquiry and wide investigation, this assumption of knowledge on insufficient premises is a prolific source of error. Regarding Asiatic cholera, many of these assumed laws require to be re-investigated, and not taken for granted.

Thus we are at present in the dark as to the mode or modes in which cholera is propagated. To take up any one side on this question is, in the present state of our ignorance, at least unphilosophical. When there is doubt, we should keep our minds open to receive any good evidence; for, on a question which is not determined satisfactorily, it is surely the part of a wise man to wait for further evidence. But, above all things, we should keep our minds free from any approach to party spirit; for, if there is any such bias, the investigator will be led rather to act as an advocate than a judge, to make out a case to prove his preconceived opinion, rather than to ascertain the truth. If he does this, he fails, and his verdict will never be registered amongst the immutable laws of nature. Some of these party men seem to fear that principles which they know are true and valuable will be endangered by the discovery of laws apparently in opposition to them. But no truths contradict each other; all laws harmonise. The communicability of cholera from one individual to another is a doctrine opposed by those who see most clearly the importance of sanitary arrangements, when, in fact, there would be no necessary contradiction to the belief in both; for, even if cholera is propagated from individual to individual, yet a *predisposition* is necessary, and this predisposition is produced by impure air, filth, intemperance, and all general bad influences which deteriorate the general health. It is a bodily state, probably an impure condition of the fluids. But this predisposition alone is not sufficient; another element is necessary. Some poison or dynamic influence is

necessary to act on this predisposed state of body; and the question is not yet solved as to what this poison or influence is, and in what mode it is communicated. Is it communicated from one individual to another, or is it the result of atmospheric or telluric influences? On this important inquiry, let us trust that the epidemic which now threatens us may be the means of throwing some light; but let no one flatter himself that the question is as yet answered. The manner in which cholera is propagated remains to be discovered. This is a point which must be kept open for investigation; and we think that those who live in small towns, villages, or country districts, are peculiarly well situated to investigate it. In the country place, it is more easy to trace all the circumstances attending the earliest cases, and the people amongst whom the disease spreads. The same medical man is probably called to every case in his district, or is aware of every case, and can make inquiries; whereas, in large places, many practitioners attend the same district, and know nothing of any cases except their own. We should expect, therefore, many more trustworthy data as to the propagation of the disease from accurate and attentive observers in the country districts, than from those in great cities, where experience (considered numerically) may be much larger. And we would suggest to those of our members who are thus favourably situated, the importance of making unbiased inquiries as to the antecedents of the first cases, and as to the persons amongst whom the disease spreads. Negative evidence is here as valuable as positive. If the same kind of searching investigation had been pursued in tracing cholera from one individual to another, as is employed by the detective police officers in tracing criminals or stolen goods, or by lawyers in detecting frauds against property by following up the suspected individual's course of life and companions for years, "leaving no stone unturned", some clearer light would ere now have been thrown on this subject, and we should not be still at the mercy of every ingenious theorist.

MILITIA SURGEONS.

In a subsequent page, we publish a letter from "A Militia Surgeon", which, we think, well merits the special attention of the class to which the writer belongs. There cannot be any doubt as to the existence of a great grievance; but, if a meeting of militia surgeons must be held before redress be asked, we fear that no relief can be expected before the Greek Calends. Let our correspondent, in the first place, discover who his colleagues are; let him then concert with the more active of their number; and so proceed, in concert with them, to draw up a form of petition to be forwarded to all militia surgeons. The forms, we predict, will be at once signed and returned ready for presentation to Parliament. A meeting might be held in London with most advantage when Parliament is sitting, and a deputation to government might then best be made to tell. The petitions, however, ought

now to be in course of preparation, and the idea of a meeting regarded as subordinate.

Although militia surgeons are more particularly the parties interested, we need hardly say that through them the whole profession is now receiving a slight and an injustice at the hands of government. As our correspondent remarks, "it is only another instance of the exaction of duties from the profession without any adequate reward." For this reason, the injustice done to the militia surgeons is not a question of mere sectional interest, but one of general importance to the whole profession. We shall be glad, therefore, to see a committee formed for the purpose of offering an efficient remonstrance on behalf of the aggrieved, and by seeing it well backed by an organisation of a large body of medical practitioners who are not pecuniarily and personally interested.

CHOLERA QUERIES ISSUED BY THE EPIDEMIOLOGICAL SOCIETY.

We have been favoured with a copy of the Cholera Queries of the Epidemiological Society, and we regret that their great length renders it impossible for us to reprint them in this number of the ASSOCIATION JOURNAL.

We cannot help thinking that the Society would elicit more replies were they to simplify and diminish the number of their questions. Many of the subordinate queries—those which refer to minute details—might be with advantage suppressed in a circular intended for general circulation, and in this way the present very formidable and repulsive aspect of the document would be removed. It would be quite easy to invite attention to all the topics by introducing paragraphs suggestive of the sort of answers which different places and different circumstances were expected to elicit. We make these remarks simply because we feel certain that the first glance which many a busy practitioner gets of these queries will make him resolve not to attempt to reply to them. By a select few, such a circular as that before us may be appreciated and responded to, but it is certainly not suited for the general body of the toil-worn medical profession.

ADVICE GRATIS TO MEMBERS OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

MUCH has been said in our columns and elsewhere about the enormous extent to which gratuitous advice is given by the medical profession, and of the rarity with which other professions and trades return the compliment. It behoves us, therefore, to record the disinterested kindness which was last week manifested towards the members of our ASSOCIATION by our esteemed friend, the eminent medical publisher, Mr. CHURCHILL. On Saturday last, he gave the following most sagacious gratuitous advice through the editor of his *Medical Times*. Speaking of the 1,300 signatures to the Albert Park petition, obtained from the medical profession by means of penny post circulars, he says:—

"Why should not representations to government, on the subject of medical grievances, be made in the same way? It would take little from the funds of any large association. Surely the money of such a society as the Provincial

Medical and Surgical Association would be more legitimately expended in making known the wants of their members in this way, than in the support of a weekly Journal which absorbs the whole receipts of the body, and obliges the Council to discontinue the publication of their *Transactions*, and apply for subscriptions to carry on the battle of medical reform."

The advice of Mr. Churchill ought at once to be acted on. Not an hour ought to be lost. Let the JOURNAL of the ASSOCIATION be forthwith suppressed; let Mr. Churchill publish, as formerly, our annual volume of *Transactions*; and let all representations regarding medical grievances be inserted as advertisements in the *Medical Times*, at £5 : 5 a page. There would be in this arrangement an obvious financial safety; as, when there were no funds, there need be no advertisements. The Albert Park advertisement, which called forth Mr. Churchill's excellent advice to our body, occupied four pages of last Saturday's *Medical Times*, and therefore cost only twenty-one pounds sterling. Perhaps, by means of a series of advertisements in the *Medical Times*, upon a scale similar to that to which we have adverted, Parliament might be induced to grant us all that we desire.

The novelty of the proposal must be accepted as an apology for not discussing it at present in more detail. We would only add, that the noble and generous course adopted by Mr. Churchill upon this occasion entitles him to our everlasting gratitude and most exalted praise.

PAYMENT OF SUBSCRIPTIONS. The Law of the Provincial Medical and Surgical Association is as follows:—

"Each Member of the Association shall pay One Guinea annually: the Subscription to commence from the 1st of January in each year, and to be considered as due, unless notice of its being withdrawn be given to the Secretary or Secretaries antecedently to the year for which it would be payable; for such Subscription each Member shall receive a copy of all publications issued for the general use of the Members of the Association."

Gentlemen wishing to join the Association ought invariably, to prevent delay and trouble, to pay their subscription to the Treasurer, or enable their proposer to do so, at the time of their election.

Letters referring to the commercial department ought to be addressed to Mr. HONEYMAN, 37, Great Queen Street, Lincoln's Inn Fields; and communications for the Editor to Essex House, Putney, London, by post. The Editor is generally at the Office on Wednesdays, from four to five p.m.

We must remind correspondents that, although they may wish their letters to appear under special signatures, it is absolutely necessary to communicate in confidence their names and addresses to the Editor.

CHLOROFORM IN MIDWIFERY. We have not room in the current volume for any more letters upon this subject.

HOMOEOPATHIC MEMBERS. The names shall not appear again in the list: and steps are now being taken in accordance with the laws for their removal.

ERRATA IN THE LIST OF MEMBERS. We particularly request that gentlemen who have discovered errors or omissions in the list published on the 21st of October, will have the kindness to send a correction of them to us within eight days from this date, so that a complete list of errata may be prepared for publication.

ORIGINAL COMMUNICATIONS.

ON THE DIAGNOSIS OF URÆMIC BLINDNESS AND DYSPNŒA.

[Excerpt from a Clinical Lecture.]

By W. H. WALSHE, M.D., F.R.C.P.Lond., Professor of Medicine and Clinical Medicine in University College, London; Physician to University College Hospital; etc., etc.

I HAVE recently seen, out of doors, a very striking example of uræmic blindness; one illustrating so plainly the occasional difficulties of its diagnosis, that I will avail myself of the particulars for the discussion of the general question.

CASE. On the 12th of November last, Mr. J. R. Wells brought me a patient of his, under the following circumstances:—

"Mr. —, aged 29, widower, leading a steady and quiet life, has generally enjoyed good health. Ten years ago, he had a peculiar contraction of the right leg, the tendons feeling stiff in the ham. Three years ago, he was ill for a fortnight with sore throat. He has now been ill for upwards of two months. A fortnight ago, boils commenced to form about his body; one, above the left orbit was followed by great pain on the spot. All of these boils got well; he felt generally ill and depressed, but was improving, when, ten days ago, he found he could not see as usual; the left eye being decidedly the worse of the two. He had no cephalalgia, nor swelling of the face.

"Nov. 12th. *Present State.* (a) He looks depressed, somewhat stupid; has slept badly for last two nights, without bad dreams; spirits low; temper of late rather morose; inclined to talk to himself. (b) The skin is pale and sallow; he does not perspire; there is no skin affection of any kind; no distinct swelling about eyelids; he says they are stiff; no swelling of ankles. (c) The legs are weak, about equally so; if any difference, the left is the worse (*vide k*). (d) Tongue tolerably clean; bowels open from medicine; anorexia. (e) Resonance is good under clavicles; no chest symptoms. (f) Heart's action is rather too extensively felt; first sound at base and apex rather too clear and full; no murmur at heart (pulse 76); strong venous hum in neck. (g) No swollen lymphatic glands. (h) Urinary organs patient declares to be in good order; three years ago, however, he had hæmaturia, for which he knew no cause. (i) Moderate headache at vertex; no vertigo; no tinnitus; no peculiar sensations of any kind in head; intellect perfectly clear; some stiffness in joints of upper extremities, shoulders most, right and left the same; he squeezes awkwardly with left hand, but about as forcibly as with right; no deviation of tongue; articulation quite distinct; no peculiar sensations in limbs. (l) No convulsive movements anywhere. (m) Pupils medium sized, round; contract immediately and gently well under light (merely that of the room); then expand a little; the action is not distinctly different on the two sides; no opacity in either eye; no amaurotic look; no photopsia; no muscæ; and no spontaneous pain in the eye-balls; no photophobia, but is pained, he thinks, by continuing the effort to see; he cannot distinguish moderate-sized objects at opposite side of the street; cannot read small print at all; sees better in morning when gets up, and with strong light; has never had diplopia."

Here, then, was an anæmic person, suffering from boils (which were, as is well known, epidemic at the time), but caring neither for his anæmia, nor his boils, nor the general disturbance of health accompanying these, but solely anxious about the sudden and increasing failure of his sight.

Were the eyes themselves diseased? No opacity could be discovered in either; membranes and humours appeared perfectly transparent. That the cornea, chambers, lens, and its capsule, were free from any change sufficient to explain the symptoms, was, in fact, unquestionable. Again, disease of the retina, producing blindness, if acute, would have been attended with local symptoms, weight and ful-

ness in the eyeball, with throbbing pain, photopsia, change of colour of the irides, etc., and with fever—conditions all of them wanting here. Chronic retinitis is attended with morbid sensibility to light, which our patient did not complain of. It is so infinitely unlikely that tumours connected with the deep seated tissues of the eye should form simultaneously in both organs, that the idea of their existence here might, almost without examining the globes themselves, be rejected. Disease of the optic nerves, or their sheaths, enlarges the pupil, paralyses the iris, and very, very rarely attacks both sides simultaneously: it was, therefore, not the cause of the blindness here.

Nor could the case be supposed one of idiopathic amaurosis. The eyes had not the amaurotic look nor expression; there was no lustre of their surface, no rolling or unsteady movements of the eyeballs, and none of the peculiar vacant gaze of that affection. This patient, on the contrary, directing the axes of the eyes appropriately, *looked as if he could see well.*

The least reflection on the condition of the patient's motor and intellectual faculties satisfies us that none of the ordinary affections of the brain could have existed here. Neither meningitis, simple or tuberculous, nor hæmorrhage, produce blindness of the type before us; and, though both acute and chronic softening do actually cause impairment of vision on one, or even on both sides, blindness never constitutes the prominent symptom it did here; besides, all other evidences of softening were deficient.

But it was not so easy to exclude tumour of the encephalon. For not only has blindness, more or less complete, been a frequent symptom in cases of intra-cranial morbid growth, but actually, next to cephalalgia, their most, or nearly their most, frequent symptom. This is true of tumours of the cerebrum, cerebellum, pons, and pituitary gland; a circumstance showing, by the bye, the vainness of the attempts to diagnosticate the seat of a cerebral tumour, solely through the perversion of special senses. It is true that there was no cephalalgia of note in this instance, but cephalalgia may be absent from first to last, even in protracted cases; and we might have been at the commencing period of the formation, at which period, there is every reason to believe, if not to be absolutely certain, the head is often free from pain. Intra-cranial tumour was, therefore, by possibility the cause of the failure of vision in this patient.

But, again, there are cases on record, tending to show that injuries to the supra-orbital nerve may produce obscurity of vision, nay, complete blindness. It is true that some observers hold that, in all such alleged cases, there has in point of fact been concussion of, or other injury to, the eyeball itself; but the weight of the evidence seems to me decidedly in favour of injury to the branch of the fifth nerve named sufficing to impair vision. Now the patient had had no traumatic mischief done to his eyebrows, it is certain; but he had had a boil there, the source of much pain and irritation; and it seemed an admissible hypothesis that the local inflammation might have acted the part of a wound in the spot. It is alleged that the nerve of one side only being implicated, the eye of the other has suffered by sympathy.

It was certain the patient had not been taking any of the drugs—belladonna, aconite, stramonium, etc.—which injure sight.* Besides, the pupils were not dilated.

Hæmic or blood-diseases (I use the adjective as more euphonious) are many of them, more or less constantly, attended with perverted vision. Now our patient was anæmic to a high degree; but I could not admit this to be the cause of his blindness; for though impairment and perversion of sight often attend this state, they never, as far as I know, do so to the extent observed here: they never constitute the prominent enduring symptom of the state. But anæmia might here be fairly taxed with increasing the blindness, though *essentially* otherwise caused.

But however plausible it might have appeared to refer

* Perry, U. C. H., Males, vol. ix, p. 105, admitted January 6th, 1853, after taking half an ounce of salts of lemon, had considerable deficiency of sight, when seen eighteen hours later.

the imperfect sight either to encephalic tumour, or to implication of the frontal nerve, examination of the urine, a few days later, furnished a much more satisfactory clue to the symptom. The fluid was highly albuminous. We now ascertained from relatives that the daily amount was small (a fact previously denied by the patient). A few days later, the eyelids were distinctly, though very slightly, oedematous; the ankles remained free from dropsy throughout. The most active measures failed to produce any secretion from the skin, which continued to the last day dry and harsh.

Between this period and that of the patient's death, on the 29th of November, one or two circumstances occurred worthy of note. The hydrochloric acid test succeeded strikingly; the expired air gave thick opaque fumes: but in this instance, as in many we have seen in the wards together, the breath was of strongly urinous odour—a state quite as significant of uræmia, as an affirmative result by Frerichs's test. For several days before his decease, the patient had *uræmic dyspnoea*, as I would call it—a dyspnoea evidently depending on the morbid state of the blood: for there was no pulmonary nor cardiac affection to explain it; the percussion-sound was excellent everywhere; there was no rhonchus, no serious alteration of the respiration-sound, and no cardiac disease. The pulse-respiration ratio averaged during this time 3:1, both pulse and respiration being, absolutely speaking, very frequent, namely 120 and 40. But there was an amount of breathing distress materially greater than attends a respiration of forty per minute: to this the poisoned blood was the apparent clue.

Now, remarkably enough, this patient remained, almost to the last moment, free from the more ordinary effects of uræmic poisoning. The brain and cord gave no sign of suffering; his intellect continued clear; there was neither delirium nor sopor; and convulsions did not occur. This dissection of the effects of the kind of poisoning in question is not uncommon: the brain and vision may alone be affected; or the vision, the functions of the spinal cord, and those of the brain may suffer simultaneously.

40, Queen Anne Street, Cavendish Square, Nov. 11, 1853.

REPORT OF THE READING PATHOLOGICAL SOCIETY.

By W. W. MOXHAY, Esq.

[Concluded from p. 996 of last number.]

DISEASES OF THE VASCULAR SYSTEM.

HYPERTROPHY OF HEART: DISEASE OF AORTIC VALVES: SUDDEN DEATH ON THE DAY FOLLOWING DELIVERY. By W. B. YOUNG, Esq. (Sept. 1st, 1852.) A married female was delivered of her seventh child on the morning of 21st August, 1852. She had a natural labour. On the following morning, she suddenly expired after taking some tea and bread and butter.

Examination of the Body. The omentum was loaded with fat, the stomach and bowels were much distended with flatus, and the liver was enlarged; the uterus was fully contracted, containing no clots; the right kidney was somewhat enlarged, but not altered in structure—the left was natural; the cavity of the chest was rather contracted, and the lungs were congested; the heart was larger than normal; the left ventricle was hypertrophied, and contained dark clots; the aortic valves were thickened and rigid; the right ventricle was small, atrophied, and quite empty.

Mr. Young considered that the disease of the heart had been the cause of death, and that its function had been arrested by the distended state of the stomach, and large size of the liver.

MIXED OR COMPOUND ANEURISM OF THE AORTA. By C. H. GAMBLE, Esq. The ascending aorta and arch were dilated to twice their natural size; while the upper part of the descending portion presented in addition a rupture of its coats, and a sac communicating with it as large as an

orange. The two upper dorsal vertebrae were eroded by the pressure, and formed a boundary to the sac; this part of it was the only one containing coagulum. The patient was a brewer's man, aged 54. He had continued his employment, with temporary intervals, until within a few days of his death. He died after excitement, which had produced rupture of the sac and effusion of blood into the right thoracic cavity. The right lung was emphysematous; it lay across the front of the pleural cavity under the sternum. Three pints or more of blood were found effused into this cavity.

DIFFUSED POPLITEAL ANEURISM. By F. A. BULLEY, Esq. The patient was W. B., a man in the Royal Berkshire Hospital, whose thigh Mr. Bulley had amputated a few days ago, on account of threatened sloughing. The man stated, on his admission on August 21st, that eleven months previously he experienced, after having carried a sack of wheat up some steps, a tingling sensation in front of the right knee. He noticed also a small swelling, not larger than a pea, in the ham; this and the tingling sensation disappeared in a few days. On the 23rd June, he again noticed the swelling, and he had some throbbing in it, and also pricking sensations up the inner side of the thigh. The tumour reached the size of a pigeon's egg. On the morning of his admission into the hospital, he was engaged in hoeing turnips; he felt something give way in the ham, and experienced rushing sensations down the leg, and up the thigh, in the course of the femoral artery. The limb became disabled, and the leg and foot numb and oedematous. The popliteal swelling rapidly increased in size, and he had sensations of burning in parts of the leg, etc. Pressure was tried by means of Mr. Bulley's tourniquet; but, the patient being obstinate, the plan was not properly carried out, and amputation became the only resource, gangrene being threatened, and the man being in a very cachectic and exhausted state.

There were found on dissection two sacs; one, the larger and posterior, contained much coagula, and was formed by the surrounding textures (fascia lata, gastrocnemii, and hamstring muscles, cellular tissue, etc.); the smaller, communicating directly with the artery through a longitudinal aperture, had more distinct parietes, continuous with the coats of the artery, but lost posteriorly in the mass of coagula of the larger cyst. The arteries were healthy above and below. The man made a slow but good recovery.

Mr. Bulley thought pressure had one inconvenience attached to it; viz., that it might damage the artery by thickening its coats, so as to render the separation of a ligature difficult and dangerous. He thought the collateral arteries had begun to dilate in this case.

Mr. MAY would limit the trial of pressure to cases of circumscribed aneurism, where the sac was entire; or where, if it had given way, a second sac had formed from the condensation of cellular tissue by inflammation.

DISEASED ARTERIES IN A PATIENT DYING OF GANGRENE. By F. A. BULLEY, Esq. (March 23rd, 1853.) Mr. Bulley presented some specimens of arterial disease taken from a woman aged 68, who had lately died in the hospital with dry gangrene of the right hand and arm. She had been exposed to cold in hanging up some clothes in her garden, and had a rigor, followed by fit, soon after. One night, having previously complained of smarting in the hand, she had great pain in it and in the wrist; she found they were of a dark colour; this change extended upwards, and had involved nearly the whole of the forearm, the hand and arm being a dry black and charred looking mass. Some of the toes were gangrenous, but there was more action in the neighbouring parts; so that the gangrenous parts were not so dry. She had for years been subject to cold extremities, shewing great feebleness of circulation.

Examination of the Body. The main arteries were examined. The right brachial artery was blocked by a firm adherent coagulum for two or three inches; the lining membrane of the artery shewing dark discoloration through this extent. The whole arterial system seemed affected

with deposits of bony and cartilaginous matter; the former being most marked at the bifurcation of the aorta into the common iliacs, and of the latter into external and internal.

DISEASES OF THE URINARY SYSTEM.

MALIGNANT DISEASE OF THE KIDNEY. By C. H. GAMBLE, Esq. (Feb. 23rd, 1853.) A child, aged two years and a quarter, had recently recovered from symptoms resembling those of acute hydrocephalus, under active treatment. The belly became afterwards tympanitic; a tumour could, however, be felt in the left iliac region, but no diagnosis was arrived at. Death by asthenia ensued.

Examination of the Body. The abdomen was found to contain a large quantity of grumous blood, which had escaped through an aperture in the peritoneum from a mass of malignant disease, which arose from the tubular structure of the left kidney, leaving the cortical substance to a certain extent untouched, but involving the colon and supra-renal capsule. The tumour, which was encephaloid and contained in the spaces left in its structure much blood, weighed five pounds; the kidney alone weighed two and a quarter pounds.

MALIGNANT DISEASE OF THE KIDNEY. By R. T. WOODHOUSE, M.D. This specimen weighed eighteen pounds; only a small portion of the cortical structure was unaffected. The tumour had occupied the whole of the right side of the abdominal cavity, and had extended itself across the spine into the left, pushing the small intestines into the left iliac fossa. The ascending colon went over the front and inner part of the diseased mass, and the ileum over the lower part, both being attached to it; the peritoneum covered the whole. The iliac, pelvic, and lumbar glands were all infiltrated with malignant deposit. The substance of the tumour was made up of a stone coloured medullary deposit, easily broken down, and having in it one or two cavities containing straw-coloured fluid. There was a cyst formed by the expansion and thickening of the capsule of the kidney, the tumour seemed to grow from the tubular structure of that organ. The left kidney was found large and congested but healthy. The history was imperfect; but the man from whom this immense mass was taken was sixty-six years old; he seems to have met with a strain twelve months ago, but dated his illness from only four months since, having been then seized with vomiting and biliousness. The legs, face, and left hand began to swell as well as the abdomen. On his admission, Jan. 26th, the tumour seemed to extend from the ribs down to within two or three inches of Poupart's ligament, and a spur could be felt going over the spine. There was a depression near the margin of the ribs, resonant on percussion; fluid existed in the abdominal cavity. He sunk by asthenia.

The urine had been examined, and was found to be sp. gr. 1022, containing no albumen. Dr. Walshe mentions, in regard to the urine, that it is unaffected in cancer of the kidney, until the renal structure is deeply diseased, blood, pus, and encephaloid matter being then found in it. In this case nothing could pass from the kidney to the bladder, on account of the ureter being obliterated by the pressure of it between the mass of the kidney and lumbar glands. Some of the diseased deposit was placed under the microscope, and was found to consist of oval cells, some of which contained nuclei; they were intersected by curvilinear fibres.

DISEASE OF THE KIDNEYS IN A CHILD. By EDWARD WELLS, M.D. (Oct. 27th, 1852.) The patient, G. K., was between two and three years of age. The mother gave the following account. On Saturday, Oct. 16th, she first noticed the child to be poorly, without any particular symptoms; on the following Tuesday, the body began to swell; but she merely thought he was getting stout; the anasarca increased. On Friday, the breathing became affected; and on Saturday, the day the child was brought to the hospital, the dyspnoea was very urgent. He died by apnoea two hours afterwards.

Examination of the Body. Very considerable serous effusion was found in both pleuræ; some in the pericardium. The heart was healthy, there was consolidation at the base of the right lung, and congestion of the liver. The left

kidney was larger than natural, the capsule readily peeled off, the exposed surface was studded with red points; the cortical substance was in a state of degeneration; the tubular was healthy. The right kidney was smaller; the cortical structure was also in a state of degeneration. The body was anasarcaous. There was no opportunity of examining the urine before death, and none was found in the bladder.

DISEASES OF THE UTERINE SYSTEM.

*** ENCEPHALOID CANCER OF THE UTERUS.** By C. H. GAMBLE, Esq. (Jan. 26th, 1853.) The specimen was taken from a woman, aged 38, the mother of nine children. In October 1851 she suffered from a profuse inodorous watery discharge, and the menstrual flow became more sanguinolent, frequent, and copious. At a time when this flow was very free, the diagnosis of cauliflower excrescence was made, a tumour filling the vagina which was crisp and friable at the lower end, but firmer above; it was attached firmly by a base larger than half a crown to the inner surface of the os uteri. Considerable bleeding followed the examination, from the tumour breaking down in its substance. Bleeding again and again recurred; in July last, one attack was so severe as to be followed by syncope of two or three days duration, since which, so much serum or blood has never escaped. Mr. G. found the alum hip bath of Dr. Ashwell the most useful remedy in checking these hæmorrhages. The pain which she had suffered in the back and hips, had been of a dull, aching character, but it now became more distressing, and accompanied with aching in the legs, more particularly the left, and in the course of the sciatics; much weight and bearing down on the perineum had also existed latterly. Symptoms connected with other organs occurred, as nausea, vomiting, diarrhoea, dyspeptic ailments, puffiness of the whole body, and incapability of being raised from the recumbent posture.

Examination of the Body. The body was found extremely exsanguine, but by no means deficient in condition. The pelvic organs were matted together; the uterus, ovaries, and cellular tissue, had much cancerous matter deposited in them; that in the centre of the uterus was tolerably firm and cut crisp; what was in the other parts was more cerebriform. There was also some malignant deposit at the vesical ends of the ureters, partially blocking up the left. A thin dirty white and slimy piece of membrane hung from the uterus.

Mr. Gamble said that in this case, Mr. May, Mr. Workman, and himself, had all agreed in the symptoms indicating cauliflower excrescence in the first instance; but he thought that the termination of the case had been by conversion of the womb, etc., into that species of cancer known as medullary sarcoma. He desired, therefore, the opinion of the Society as to whether this was a natural termination or an accidental complication; in a case where life had been unusually prolonged. Mr. May expressed his opinion that cauliflower excrescence and encephaloid cancer were identical; and Dr. Wells also thought that cauliflower excrescence was a malignant disease.

UTERINE POLYPI. By G. MAY, Esq. (April 20th, 1853.) An unmarried lady, aged 45, had for six years had occasional uterine hæmorrhage. In consultation with Mr. Stone, a small tumour was found, and tied. She still suffered from periodical floodings, which reduced her very much. A second pedunculated tumour was found, which gradually descended into the vagina; this was surrounded by a stout ligature, which, after some days, broke. The peduncle was nearly ulcerated through, and the tumour soon came away (about a fortnight before death). On the 18th instant, while about her household affairs, she was seized with vomiting, diarrhoea, and shivering, with pain in the abdomen. She appeared death-struck, and died on the 19th.

Examination of the Body. The peritoneum, over the

* A case of Internal Uterine Hæmorrhage was related by Mr. Harrison, but as it was published in the ASSOCIATION JOURNAL for January 7th, it is not necessary to reproduce it here.

small intestines, was found vascular; and there was slight serous effusion into the abdominal cavity, with a few flakes of lymph. The vagina and cervix uteri were healthy; the seat of the polypus showed only a slight projection—no inflammation nor ulceration. The body of the uterus was greatly hypertrophied, weighing $2\frac{1}{2}$ lbs., with several nodules of various sizes projecting from its surface. There was a small pendant polypus within the cervix, about an inch in length; and, on laying open the cavity of the uterus, a larger one was seen hanging from the fundus, $2\frac{1}{2}$ or 3 inches in length. The peduncles were pale, but the bulbous heads purple and flaccid, as if composed of turgid vessels. A question arose as to the malignancy of the tumours in the walls of the uterus; but the general opinion seemed to be, that they were fibrous and non-malignant. They were perfectly smooth, almost globular, and slightly elastic to the passage of the knife, the section giving a distinct fibrous appearance.

DISEASES OF THE CUTANEOUS SYSTEM.

LUPIN-SEED FAVUS. By E. WELLS, M.D. (June 30th, 1852.) Dr. Wells presented wax models and a drawing of a specimen of the lupin-seed favus, extending over the whole body, which had existed in a little girl in the hospital. The disease had yielded to alkaline baths every night, of six ounces of carbonate of potash, in thirty gallons of water at 98° . The portion of the disease on the scalp was treated with equal parts of sulphur ointment, and tar ointment, and alkaline lotions. Dr. Wells remarked, that the disease began in small points, which coalesced and formed patches. Some of the smaller of these much resembled a section of calumba root. He also stated, that favus in the scalp often got well under simple poultices. These were, at any rate, absolutely necessary, before stimulating applications were used. Three of this patient's brothers were, it seems, affected with the same disease in the scalp.

CUTANEOUS CANCER. By I. HARRISON, Esq. (Sept. 1st, 1852.) Mr. Harrison presented a cast of cutaneous cancer in the neighbourhood of the left eye, taken from a man aged 92. Mr. Harrison thought this man's death had not been in any way accelerated by it. He died by asthma. Mr. H., however, recommended the early removal of tumours of the face; as, he thought, they always degenerated into malignancy. He mentioned a case in which Sir A. Cooper had been consulted, and had advised non-interference, but in which cancerous degeneration had since taken place.

Mr. MAY referred to the case of the clerk at Sonning church, in whom an epithelial cancer had existed thirty years, and had now destroyed the cheek. He thought that, in this form of disease, the neighbouring tissues were tolerably free.

In surgery, there has been little brought before the Society. The few cases relating to this subject I have thought it better to place amongst the diseases of the different systems to which they belong, finding it very difficult to distinguish where medicine ends and surgery begins. I may refer, in proof of the necessity of their existing together, to the two cases of operation by Mr. May. In these, what would have been the value of the attendance of a man endowed merely with the knowledge of external disease and hand work? In his most anxiously treated case of artificial anus, the symptoms brought to him the knowledge of some hidden grave obstruction somewhere in the intestinal canal, and his knowledge of hand-work enabled him to find and use the probable remedy.

We might hope for greater advances than even have been made in our capability of distinguishing disease, but more particularly in our capability of advising our patients well as to some of the dangerous operative proceedings they are to undergo, if all our brethren were induced to adopt the practice of reading their unsuccessful as well as their successful cases. Doubts are thrown on the results of the ovarian section, and its justifiability as a surgical operation, by the non-appearance of facts which, though they

may, in the eyes of some, militate against the reputation of an individual, would make easier the path of many an anxious member of our profession in his endeavours to relieve suffering humanity.

Reading, September 1853.

TWO CASES OF VIOLENT INFLAMMATION OF THE PENIS, CAUSED BY CONSTRICTION WITH STEEL RINGS.

By S. T. CHADWICK, M.D. Edin.

ALTHOUGH the following cases may not possess much practical value, their unusual occurrence may render them of sufficient interest to merit being recorded.

CASE I. A farmer's son, aged 7 years, residing in the neighbourhood of Standish, was brought to me on a Tuesday morning, in consequence of what his parents (who accompanied him) stated to be an inflammation about his private parts.

On examination, I found the penis prodigiously swollen, tense, and inflamed; and, on the least attempt at manipulation, he involuntarily receded, and screamed out from pain, which was evidently of an agonising character. I was astonished on observing the defined form of the swelling, which abruptly terminated near the root of the penis, at which part there was a grooved appearance that completely encircled the organ; and on forcibly pressing the swelling to one side, I thought it was surrounded by a tight ligature. After urging the boy for an explanation, he for the first time gave a narrative, from which the following facts were gleaned; viz. that on the evening of Sunday he was in one of the outbuildings, amusing himself by attempting to pass a metallic ring over the penis, which, after some difficulty and perseverance, he effected, and very shortly after accomplishing it, he was called into the house by a servant, to partake of supper and be put to bed. In the course of the night he awoke from a feeling of uneasiness; and then, for the first time, he made an attempt (which was ineffectual) for the removal of the cause of the inconvenience. He passed a restless night; and on rising in the morning, he complained of indisposition, so much so, that he was kept from school. During the day he got worse, refused his food, became feverish and restless, was frequently sick; but it was not until evening that he directed his mother's attention to the seat of his suffering. She informed me that at that time there were considerable swelling and inflammation, and she commenced fomenting with a decoction of herbs, and gave him a potion of some domestic cathartic. These means, however, afforded him no relief; the night was passed without sleep, and there was occasional delirium. In the morning, the case had assumed an appearance so alarming, that he was brought over in a spring cart to my surgery, attired in girl's apparel, as he could not endure the contact of his own clothes.

As a similar case had never before come under my observation, I felt exceedingly perplexed how to proceed under the circumstances. By means of several scarifications, which were followed by a copious discharge of blood and serum, and the use of an evaporating lotion, the swelling and sensibility were diminished, and thereby a greater tolerance of handling was the result.

An ingenious mechanic, who chanced to be present, suggested the possibility of the ring being snapped with a powerful pair of forceps or pliers; but the difficulty that presented itself was the deep sulcus in which it was imbedded. Nevertheless, after the lapse of considerable time, we succeeded in breaking the ring on each side, by the means alluded to above.

An emeto-cathartic mixture was ordered to be administered, and warm water dressings kept assiduously applied to the parts.

CASE II. The second case was the son of a nail maker from Atherton, aged 8 years. This case also was produced by

similar circumstances, and presented almost the same appearances; it is therefore unnecessary to go into any lengthened detail. In addition, however, there were several vesications at the end of the prepuce, retention of urine, the distended condition of the bladder being evident in the hypogastric region. The same plan of treatment was pursued, and the removal of the foreign body was equally painful and protracted. The difficulty of both operations was greatly augmented by the utter impossibility of restraining the writhings of the sufferers. It was gratifying to witness the sudden amelioration of both the general and local symptoms, following almost immediately on the removal of the exciting cause. In a few days, the patients could move about the room; and before the expiration of a month, the only abnormal appearances observable, were some thickened condition of the integuments, and marks left by the abrasion produced by the rings.

Had the constriction not been removed, it is evident that gangrene must have very shortly ensued.

The induction of anaesthesia would doubtless very materially have facilitated the various steps of the operation, and also have saved the children much torture; certainly, should I meet with another case, I shall resort to its agency.

Bolton-le-Moors, Lancashire, November 10, 1853.

CASE OF TRACHEOTOMY; WITH REMARKS.

By CHARLES WEBB, Esq.

AT 5 P.M., Sept. 5th, I was called to see a fine stout child, aged two years and two months, who had inhaled the steam from the spout of a boiling tea-kettle, a few minutes before I arrived. On examining his mouth and tongue, I found no blisters. I advised the mother, if she found the breathing affected, to apply bread and mustard poultices to the throat, and give him small and repeated doses of oil, and to let me know if she saw any change. About eleven o'clock the same night, my assistant being in the neighbourhood, I got him to call in and see the child. He found him heated and restless, and some difficulty of breathing. I gave him an aperient powder and an antiphlogistic mixture, and applied two leeches, which bled freely, without relief. A little before five the next morning, I was informed that he was much worse; and, on visiting him, I found his lips blistered from the steam. He was perfectly insensible; his breathing was most laboured and gasping, as if the glottis were all but closed.

Under such circumstances, not a minute was to be lost; and I proposed the operation of tracheotomy, which was at first refused by the parents. I told them there was no time for delay, as it was the only chance of saving the child's life. With their consent, I immediately operated. Directly the trachea was opened, the breathing was instantly relieved. The child had been for some time troubled with a cough, and a good deal of mucus escaped from the opening. Having no tracheal trocar or canula, I used a common dressing case-knife, and enlarged the opening of the trachea with a blunt topped bistoury, and inserted a hydrocele canula; but, from the spasmodic coughing, it could not be retained. After waiting more than an hour, I obtained about two inches of a No. 9 catheter, and introduced it. This for a few minutes produced considerable irritation, and the expulsion of a great quantity of mucus. After this, he fell into a sound sleep, and slept for three hours, when he awoke up quite conscious and refreshed, and made his mother understand that he wanted drink. I had ordered cold thin gruel to be ready for him when he required anything, and he drank freely and frequently of it, and continued to do so for a week, and nothing else. He continued his mixture, and progressed daily, without a bad symptom, to recovery. The canula was removed several times to be cleaned, and it was withdrawn altogether on the 13th. The wound closed up in a short time, and was completely healed on the 2nd of October.

REMARKS. I have only to make some remarks on the operation to any one who may be placed in my situation, not having instruments proper for it at hand. After cutting through the skin, remove the fat which fills up the opening with a pair of forceps and scissors; by doing so, the wounding of vessels and hæmorrhage are avoided; and the trachea, being laid bare, will give a clearer sight for the insertion of the knife. Had I not done this, the operation would have failed, as the child would have been suffocated with blood and mucus, although he did not lose more than half an ounce of blood during the time I had to wait for the canula. The space being clear, I could wipe away both, with a cold sponge, as fast as either appeared.

Basingstoke, November 10th, 1853.

BIBLIOGRAPHICAL NOTICES.

HANDBOOK OF ORGANIC ANALYSIS. By JUSTUS LIEBIG, Professor of Chemistry in the University of Munich. Edited by A. W. HOFMANN, Ph. D., F.R.S., etc. London: 1853.

BARON LIEBIG, in his prefatory remarks to this book, acknowledging the assistance received by him from Dr. Strecker of Christiana, and Dr. Hofmann, his present editor, gracefully says, "I believe the cooperation of my friends, who possess so much experience in that department of chemical analysis, 'the organic,' has conferred a peculiar value upon this little work." To Liebig, however, we cannot but ascribe the simplicity and clearness pervading this Handbook, (and which, when he pleases, are the characteristics of his style,) as well as the excellent general arrangements, so plain and easy to be comprehended, that the student must be obtuse indeed who cannot understand and follow the directions without difficulty, after some slight practice in manipulation.

We can readily imagine that "the peculiar value" referred to, as due to Drs. Hofmann and Strecker, consists in what the former calls "little improvements"; being in truth the details of those seemingly trifling precautions, and the methods for making, arranging, and using various simple apparatus, without the careful observance and use of which, success in organic analysis is unattainable. With such "little improvements" every page is studded, lending most truly "a peculiar value to this little work;" its smallness being, in our eyes, not the least of its merits.

Whatever may respectively belong to each author as his special deserts, we cannot speak too warmly of the manner in which the triumvirate has produced the useful *vade mecum* before us. We particularly thank Dr. Hofmann for his successful adaptation of coal-gas to the purpose of organic analysis, an arrangement of especial benefit to the chemists of this country. To point to the pleasant rendering of the original into our language is almost superfluous, the editor being, as it were, naturalized amongst us, and we, moreover, remembering a very successful exercise of this faculty on a former occasion, and on a more difficult subject. The engravings are unusually distinct and good; and we are glad to see that the accessories of paper and type are such as should always be bestowed on a useful and original work, especially if it be one intended for hard service.

PRACTICAL PHARMACEUTICAL CHEMISTRY. By DR. G. C. WITTSTEIN. Translated by STEPHEN DARBY. London: 1853.

MR. DARBY's command of his mother-tongue is not evidenced in this translation. He pleads, indeed, in extenuation, that it was executed in the hours of relaxation from business: but we cannot see the force of this excuse. When he was at work, he might as well have done it thoroughly as indifferently. "Whatever is worth doing, is worth doing well."

He has, however, evinced much patient determination, resolute labour, and praiseworthy accuracy in the performance of his task, and has produced a book which, if the manufacturers of therapeutical chemicals can be induced to study it, is likely to be very useful to most of them.

We do not think the work will add to Dr. WITTSTEIN'S reputation in this country. As a collection of facts and a book of reference in the library, or in the pharmaceutical laboratory, it will prove valuable; but it is wearisome, spun-out, and pedantic; there are upwards of nine pages devoted to the trumpery preparation of *Ferrum oxidatum hydraticum*, as it is termed. Indeed, these barbarous repellent names run through the book. Who would recognise "Lead plaster" when masquerading as *plumbum oxidatum margariticum et oleinicum*? Should this translation reach a second edition, Mr. Darby would greatly increase its value were he to condense his author's text, and substitute the English names of the preparations, as he has wisely done in the index, for the wretched pedantry which now heads the pages.

A HANDBOOK OF INORGANIC CHEMISTRY. By WILLIAM GREGORY, M.D., F.R.S.E., Professor of Chemistry in the University of Edinburgh. Third Edition. London: 1853.

We have here an old friend under a new name; this "Handbook" being "A new and greatly enlarged edition of the *Outlines of Inorganic Chemistry*"; and being also, what we can seldom say of books of this class, greatly improved by the enlargement. We well remember that the very brevity of the "*Outlines*", i.e., of the first edition (we do not think we ever saw the second) vexed us; brevity was there, seemingly, the one thing needful in the author's eyes, and utility itself was sacrificed to it. In its present shape, this grave though rare fault is remedied; nor is it often our fate to meet with a book which, with fair diligence on the part of its reader, can so well realise the promise upon its titlepage, "For the use of Students". A young man, who has mastered these few and by no means closely printed pages, may venture to face any board of examiners on chemistry without fear of being posed by any fair questions.

Were we required to name a book which should convey to the reader, in the most simple and terse manner, a sound and general knowledge of chemical science, we should unhesitatingly say "Gregory's Handbook". The pleasant simplicity, easiness, and even elegance of style, continually remind us of the "Manual" of the late amiable and talented Dr. Edward Turner; a book which was our own guide to the shrine of chemistry. We have no higher praise.

PERISCOPIC REVIEW.

MICROSCOPICAL DISCOVERY.

THE CELL-THEORY.

The *Edinburgh Philosophical Journal* for October contains the summary of a lecture on this subject by Mr. THOMAS H. HUXLEY, in all the conclusions of which we cannot coincide, but which is well worthy of notice. It is entitled *On the Identity of Structure in Plants and Animals*; a structure distinguished from that of unorganised bodies by being neither chemically nor optically homogeneous, but composed of small definite masses, containing a large quantity of nitrogen, imbedded in a homogeneous matrix having a very different chemical composition. These nitrogenous bodies (called *endoplasts* by our author) may be more or less solid or vesicular, and are the "nucleus" of animal tissues, or the "primordial utricle" in plants. The matrix (or "periplastic substance") readily breaks up into definite portions surrounding each endoplast, and its modifications form the other histological elements of the tissues.

Upon this view we find that all the discrepancies which had appeared to exist between the animal and vegetable structures

disappear, and it becomes easy to trace the absolute identity of plan in the two; the difference between them being produced merely by the nature and form of the deposit in, or modification of, the periplastic substance. In both plants and animals, then, there is one histological element, the endoplast, which does nothing but grow and vegetatively repeat itself; the other element, the periplastic substance, being the subject of all the chemical and morphological metamorphoses, in consequence of which specific tissues arise.

The part of Mr. Huxley's paper, however, in which we cannot agree, is that in which he denies all vital force to the "cells" themselves, as being merely "periplastic". Now we submit that the very metamorphoses he describes prove the existence of such "cell-force", whether we reckon it chemical, mechanical, both, or neither. "Suppose", says Mr. Huxley, "that one, ignorant of the mode in which a house is built, were to pull it to pieces, and find it to be composed of bricks and mortar, would it be very philosophical on his part to suppose that the house was built by *brick-force*? But this is just what has been done with the human body; we have broken it up into 'cells', and now we account for its genesis by *cell-force*." Now we shall only say, that whenever Mr. Huxley shall exhibit a house in which the bricks are "the subject of chemical and morphological metamorphoses, in consequence of which specific tissues arise", granite, freestone, slate, and marble, appearing in gradually increasing masses as this wondrous development goes on—when the street and the number of this house are pointed out, then shall we admit the analogy: and as these strange changes are in progress, "may we be there to see."

Dr. MARTIN BARRY has published, in the same Journal, three "notes", respectively concerning the twin spiral filaments long ago described by him as the origin of every structure in the body; the entrance of spermatozoa into the ovum; and the formation of the ovum.

With regard to the first question, Dr. Barry holds to the spiral fibre theory in all its integrity, and claims the recent support of Agardh to uphold it, in as far at least as the vegetable tissue is concerned. As we are not prepared to give in our adhesion to this theory, we merely quote in brief the expression of it, that our readers may understand the question. "The prime mover is the *nucleolus*, which is the organ of absorption, secretion, and assimilation; the nucleolus always passes into fibre, and directly into no other form than that of fibre; and then the whole organism arises out of nucleoli, for fibre is but the nucleolus in another shape, and every structure arises out of fibre."

THE OVUM.

Dr. BARRY is led to the following conclusions with reference to the structures connected with the ovum in different animals:

1. That in mammalia the vesicle he described as the foundation of the Graafian vesicle, and termed the *ovisac*, does not remain permanently in the ovary, but is expelled and absorbed.
2. That in the bird this *ovisac* becomes the shell-membrane of the egg.
3. That after the formation of the ovum, the albuminous contents of the *ovisac* in mammalia correspond to the albumen in the bird's egg.

COLOUR OF THE HAIR.

The same Journal contains a paper on this subject by Dr. ALLEN DALZIELL, wherein he concludes as follows:

The colour of the hair depends upon one or more of three causes:

1. On *pigment-granules*, of which our author has assured himself that the pigment is never lodged exteriorly in the cells, but always in some part of the interior; and changes, during the growth of hair, often take place at regular intervals in the colour and amount of these deposits.
2. On *diffused colouring matter* impregnating the whole tissue, a good example of which may be found in the short hairs from the face of the hare.
3. On the presence of *air-spaces* within the fibres of the shaft, which refract light, and thus give the idea of colour; these are best seen in white hairs.

THE CORPUSCULA TACTUS.

Mr. HUXLEY has published, in the *Journal of Microscopical Science* for October, some interesting observations on those remarkable bodies, which we have twice introduced to the notice of the readers of this JOURNAL, and upon which, as we need not enlarge, further than just to state that they are Huxley's researches.

1. He has found in the human finger papillæ containing both corpuscles and vessels, though never any destitute of corpuscles, and yet containing nerves. It follows that the distinction originally made by Wagner into corpuscular and vascular papillæ cannot be absolutely maintained.

2. He believes that the corpuscle is not histologically a special structure, but is composed of tissue not radically different from that of the papilla itself, the sole difference consisting in this, that the elastic bands and filaments which the corpuscle contains are more or less parallel to one another, and perpendicular to the axis of the corpuscle. In one respect, however, he believes the corpuscles to be peculiar, namely, that they are the modified extremity of the neurilemma of the nervous tubules which enter the papilla.

3. Without positively denying that the nerves may end in loops, he states that he has never been able to convince himself of this mode of termination; and that, on the other hand, he has frequently observed the nervous tubules to end by pointed extremities, which appear to be continuous with the tissue of the corpuscle.

4. He considers the corpuscles in question as analogous to the Pacinian bodies, in which latter bodies he denies the existence of concentric laminae and of a central cavity, and considers them as nothing more than thickened processes of the neurilemma of the nerve to which they are attached, differing from the tactile corpuscles only in the circumstance that the thickening in the latter takes place on each side of the nerve fibril, while in the Pacinian body it takes place on both sides.

FUNGOID PARASITES OF THE SKIN.

C. MEISSNER has described, in the *Archiv für Phys. Heilk.* 12, 193, a new fungus, which he observed in the *finger-nails* of an old man. The nails were very thick, curved, yellowish white, and streaked; and, on examining them carefully under the microscope, they were found to be full of a rich plexus of variously convoluted filamentary fungi, which in many places formed a thick felt among the cells of the nail-substance. The toe-nails were unaffected.

When asked respecting the nails and the cause of their alteration, the old man stated that about thirty years previously a heavy weight had fallen upon his fingers, in consequence of which the nails were broken, and had come off; that they subsequently grew again, but had gradually become thick and white.

The last number of the *British and Foreign Medico-Chirurgical Review* contains an interesting review of M. ROBIN'S *Natural History of the Vegetable Parasites which infest the Bodies of Animals*, in which mention is made of about two dozen of these organisms as occasionally found on the human body. We think that, for practical purposes, it will be enough to notice the following fungoid denizens of the skin.

1. In the true favus, well known by its yellow crusts, we have the now familiar *achorion Schönleini*, the tubes and spores of which are found in the hair follicles surrounding the root of the hair, and passing out on the surface of the skin, where they form the familiar favous crusts of this "porrigo scutulata."

2. In ringworm of the scalp, or trichosis furfuracea (Wilson) we have the *trichophyton tonsurans*. The disease is distinguished by the bald patches being rough with the swollen and brittle stumps of the diseased and broken-off hairs; and the fungus, consisting of oval transparent spores and articulated filaments, is seated in the interior of the roots of the hairs. "The hairs and fungi simultaneously increase; the former seem larger than usual, are paler in colour, lose their elasticity, soften and break off when they have risen some one or two lines above the surface of the scalp; in the short cylinder then left the fungus grows still more rapidly, so that the normal structure of the small stump of hair soon becomes indistinguishable. Sometimes the hair breaks off before emerging from the skin, and the fungus, epidermis, and sebaceous matter, fill the ends of the piliferous conduits, and form the little prominences which can be seen by the naked eye in this disease, and give the skin a rough aserine appearance. The sporules and mycelium of the plant can sometimes be seen in the form of a white powder, on the roots of the broken hairs."

3. In porrigo decalvans, or alopecia circumscripta, is found the *microsporon Audouinii*, distinguished by its numerous waved filaments, and the extremely small size of its sporules. It is not found, like the *Trichophyton*, in the interior of the root, but forms round each hair a little tube; the hair then becomes opaque, softens, and breaks off. The alopecia is rapid, the dermis is not congested, and the epidermis is thin and smooth.

4. In mentagra grows a plant resembling the preceding, but possessing larger spores and filaments, yeilded the *microsporon mentagraphyta*. Its seat is between the bulb of the hair and the follicle in which the bulb is seated; and it never extends beyond the surface of the skin.

5. The brown scurf of the disease called pityriasis versicolor, or chloasma, is formed by another cryptogamic plant, the *microsporon furfur*.

The essential point in the treatment of all these diseases is to destroy the vitality of the parasite, by means which are pretty equally applicable to all of them. If hairs be present, as in most of the maladies above described, they must be removed by extraction, with or without previous application of some of the usual depilatory ointments; and then some "parasiticide" solution or ointment must be applied and rubbed into the skin, so as to reach the fungi in the recesses of the follicles. A solution of corrosive sublimate, two grains to the ounce; an ointment of acetate of copper, one grain to the ounce; and, above all, the saturated aqueous solution of sulphurous acid gas, diluted with two or three parts of water, may be used for this end. In cases of mentagra, we have found an ointment of sulphate of iron, 3ss to the ounce, completely effectual in curing the disease. There are no doubt many other substances which have a similar good effect; but a caustic such as nitrate of silver, which, by forming a crust on the surface, rather protects the fungus than destroys it, will not succeed.

CRYSTALLISATION OF THE BLOOD.

A new and very interesting subject has lately been more formally brought before the profession; we refer to the fact of the production from the blood, in certain circumstances, of red "albuminous crystals", which, though formed of animal matter, and sometimes, in all probability, during life, have yet forms as regular as any inorganic crystals. An excellent epitome of the facts bearing upon this matter has been published in the *Medico-Chirurgical Review* for October, from which we select as much as appears calculated to be interesting to the majority of our readers.

It has been hitherto held to be the rule, that crystallisation is peculiarly a property of inorganic chemistry, and that crystalline forms are met with in the animal economy only when the material giving rise to them has lost all claim to be considered as an integral part of the living tissues. The discovery of the crystallising power of the albuminous elements of red blood (*hematoidin* of Virchow) has, however, made it probable that there are exceptions to this general law.

Various authors, as Sir E. Home, Scherer, etc., had described reddish crystals in blood which had been effused into tissues or organs; but Virchow was the first who paid particular attention to their actual nature, as different from saline or earthy crystals. He considers that the formation of these red crystals is the terminal step of the transformation of the colouring matter of the blood, which, first diffused, passes into the granular, then into the crystalline form; the crystals being yellowish or red, of a rhomboidal form, occasionally as large as the ordinary triple phosphate crystals in the urine, and forming spontaneously in extravasated blood, in the course of from a fortnight to three weeks after its escape from the vessels. Virchow concludes, that the crystallising process may take place—1, in the cells; 2, in amorphous protein substances (in both cases from diffused colouring matter); or 3, from agglomerated and subsequently metamorphosed blood-corpuscles; that the crystallising power is inherent in the albuminous matter or protein; and that the colouring matter in the crystals bears no other relation to them than the metallic colours impregnating its crystals do to quartz. Reichert comes to similar conclusions: that the crystals are albuminous, and that the colouring matter is not an essential feature. Kölliker has advanced another step in this investigation, having detected the crystals in the interior of unbroken blood-corpuscles. In the blood of a dog's liver, he found a great number of blood-globules, containing from one to five rodlets of a dark yellow colour; and, in unchanged corpuscles from the splenic blood, the gradual formation of one or two of the crystals could be followed. Dr. Funke introduces the matter under yet a new aspect: he has succeeded in forming the crystals from the blood. If we add water to a drop of blood spread out upon the object glass of the microscope, when the drop has just begun to dry up, the edges of the heaps of blood-corpuscles are seen to undergo a sudden change. A few corpuscles disappear, others receive dark thick edges, become angular and elongated, and are extended into small, well defined rodlets. In this manner, an enormous quantity of crystal embryos are formed, which are too small to enable us to determine their shape; they rapidly

extend more and more lengthways, the entire field of vision being gradually covered with a dense network of acicular crystals crossing one another in every direction, other crystals presenting the form of rhombic plates.

The coloured rhomboidal crystals, however, as originally described by Virchow, do not appear to be capable of being artificially formed.

Such, we think, is a correct, though brief statement of the principal facts on this very interesting subject.

On referring to the drawings of some of the principal forms which we have already described, we think no one can fail to be struck with their great resemblance to the various crystalline forms found in the urine, uric acid, oxalate of lime, triple phosphate, nay, even cystine. Had we been shown the drawings without being told of their origin, we should at once have set them down as illustrations of the crystalline urinary deposits.

MODE OF TERMINATION OF THE NERVES.

From a paper by RUDOLPH WAGNER, in the *Annales des Sciences Naturelles*, xix, 370, we extract the following statement of that distinguished physiologist's late researches on this much vexed subject. His investigation has been carried on chiefly in relation to the ending of the nervous filaments in the dental pulp, the papillæ of the tongue, and the labyrinth of the ear.

In the tooth-pulp, the nerves end by free extremities; and though they form loops in great number, yet the same fibril may be traced through several loops, and appears always to terminate at last by a free ending. In the lingual papillæ, too, the termination by loops is apparent only, and the deception arises from the mere superposition of one curving fibre over another, each afterward pursuing a separate course, and ending free.

In the labyrinth, Wagner observes, 1, a system of fibres, manifestly ending by free extremities; 2, a set of looping fibrillæ; 3, another system of fine branching fibres; the connexion between which three systems is not easily traced. He concludes "provisionally", that the auditory nerves consist of primitive fibres, interrupted in their course by the frequent insertion of "ganglionic cells", which, connecting the ends of the interrupted fibre, are necessarily attached by each end, or "bipolar"; that these fibres then form with the loops a terminal plexus, next pass into the condition of pale thin fibres (without the medullary pulp), and that these ramify; and that, at the extremity of each branch, there is seated a ganglionic cell, fixed on it "like a pear by its stalk", and hence "unipolar".

Wagner concludes also, from his examination of the nervous fibres of the lachrymal gland, and of muscle, that all the primitive nervous fibres, motor, sensory, and "trophic", subdivide many times, and never form terminal loops; that free ending of the nervous fibrils is the general rule, and that to these fibrils are attached either the elements of the tissues, or, as appears to occur in many cases, ganglionic (nervous) cells, forming as it were "terminal buttons".

This conclusion with respect to the termination of the nervous filaments by free extremities, and the absence of proof, to say the least, of the ending being by loops, manifestly tallies with the observations of Mr. Huxley above detailed.

SURGERY.

STATISTICS OF TETANUS.

In the *Glasgow Medical Journal* for October 1863, Dr. J. A. LAURIE has published an instructive statistical record of cases of tetanus. In commencing, he makes the following remarks:

"When lecturing on tetanus, I have found it necessary to say that, while we knew it to be one of the most fatal of secondary surgical diseases, we were not in possession of data by which the ratio of its mortality could be ascertained. On this point, the inferences drawn from any tables which I have seen, especially that of Mr. Curling, are most fallacious; for the obvious reason that the tables, being made up of published cases, a large proportion of which are recorded because they are recoveries, give results which fall far short of the actual mortality. In the hope of supplying this desideratum, I turned to the records of the Glasgow Infirmary. The results of that investigation form the groundwork of this communication. It is only by a careful and truthful record of all the cases which occur in large hospitals, that accuracy on this and many allied subjects can be arrived at. After a very careful search through the

records of our Infirmary, from its commencement in 1794 to the present month, I have been enabled to construct the following table. In consequence of some of our records being lost, and others imperfectly kept, it does not contain all the cases of tetanus which have been admitted into our hospital, or have occurred within its walls, but it contains all I could find; and seeing that it has been constructed solely from the journals of the hospital, consisting of daily, sometimes hourly reports, taken at the bedside of the patients, by numerous observers, at long distant intervals, I am certain it is as accurate as any table of the kind well can be. For these reasons, it is more valuable than any table of cases of tetanus that I have met with. There has been no selecting, no recording, because the patients recovered, but all are given.

"To show that I do not undervalue the labours of those who have searched for and arranged 'published cases', I have prepared a table containing 171 such cases, the largest, so far as I know, yet recorded. My object in so doing, was partly to confirm some of the conclusions which I have drawn from our Glasgow cases, and partly by contrast, to show how little, as regards prognosis, and the results of treatment, inferences drawn from published cases are to be relied upon. In preparing this table, I have been greatly assisted by that published by Mr. Curling, in his *Essay on Tetanus*. Of his table, I have made liberal use; but I have not taken a single case on trust. I have examined the authorities for all the cases contained in it, and have added some particulars, especially the months in which the cases occurred, which are not given by Mr. Curling."

Then follow two tables; one of fifty-two cases—fifty traumatic, and two idiopathic—compiled from the records of the Glasgow Infirmary; and another, of one hundred and seventy-one cases, from other sources. The particulars in the tables are arranged under the following heads:—number of cases, name of patient, sex, age, nature of injury, state of wound at first symptoms of tetanus, month and year, date of appearance of symptoms after injury, duration and result, and treatment; and in the table of published cases, references to the authorities are given.

Dr. Laurie then gives a summary of the facts contained in the tables.

"Years in which the Glasgow cases occurred. In 1797, one case; 1802, one; 1804, one; 1807, two; 1808, one; 1809, one; 1813, one; 1814, two; 1817, one; 1818, one; 1820, one; 1824, one; 1830, five; 1831, one; 1832, three; 1833, one; 1839, one; 1840, one; 1841, two; 1842, one; 1843, one; 1845, two; 1846, one; 1847, five; 1848, two; 1849, three; 1851, one; 1852, two; first six months of 1853, four. Of the idiopathic cases, one occurred in 1844, and one in 1853.

"I do not pretend to give all the cases which have occurred in the hospital; but as I have given all that I could find, I have at least made an unbiassed approximation to the truth. So far as it goes, the table confirms a statement which I have frequently made, that tetanus at times assumes almost an epidemic character. I have had as many as three acute cases under treatment at the same time. In 1847, the table gives five cases; in 1849, three; and in the first six months of 1853, five.

"Months in which the cases of tetanus occurred:—

	Pub. cases.	Glasgow cases.	Total.
January -	16	6	22
February -	12	5	17
March -	10	6	16
April -	12	4	16
May -	18	5	21
June -	8	3	11
July -	11	5	16
August -	13	1	14
September -	7	4	11
October -	22	7	29
November -	19	2	21
December -	19	2	21
Not stated	6	..	6
Total -	171	50	221

"An opinion has long been entertained, that tetanus is more common in hot than in temperate and cold climates; and in Europe, that it is more frequent in summer than in winter. Alternations of temperature have also been supposed to have great influence in its production. On this subject, *Lévesque* (*Clinique*, tom. i, p. 90), that the wounded exposed to the moist air of 'les vents nord—nord ouest, surtout par

temps, contractent facilement le tétanos; cet accident au contraire paraît rarement lorsque la température est à peu près égale, soit en hiver, soit en été.' A statement nearly similar is made by Dupuytren, and by many English writers. Our tables do not fully confirm these opinions. Taking the Glasgow cases as the most correct, we find that August and June, two hot months, give four, while January and February give eleven. If we arrange the months into four cold, January, February, November, and December, we find fifteen cases; four warm, May, June, July, and August, we have fourteen; and four temperate, March, April, September, and October, we have twenty-one. When we turn to the published cases, we find the four winter months give sixty-six; the four summer, forty-eight; and the four temperate, fifty-one. Thus, both tables combined make the disease least frequent in summer, and most common in winter. The individual months show considerable eccentricity, but still confirming the same inference, January being one of the largest, June and September the two smallest.

"Has season any influence on the mortality of tetanus? In the Glasgow table, the number of recoveries is so small, that almost necessarily those months which show the largest number of cases exhibit the greatest amount of mortality—two recovered in January, and one in April, May, June, and October, each. Of the ninety recoveries in the published cases, there were in January six, February eight, March six, April eight, May ten, June four, July six, August ten, September four, October nine, November eight, and December eleven. If we arrange the months, as we have already done, we find the four cold months give sixty-six cases—of which thirty-three recovered, and thirty-three died; the four temperate months, fifty-one, of whom twenty-seven recovered, and twenty-four died; the four summer months, forty-eight cases, with thirty recoveries, and eighteen deaths. It would thus appear, that the winter months give the largest number of cases, and the highest ratio of mortality; while the four summer months give the fewest cases, and the smallest ratio of fatality.

"Sex. Of the 50 Glasgow traumatic cases, 41 were males, and 9 females; the proportion being 4½ males to 1 female. The table of published cases contains 144 males, and 27 females; the proportion being 5½ to 1. By Mr. Curling's table, the proportion of males to females is 8 to 1. The Glasgow tables give a proportion of nearly one-half of this; and, for the reasons already stated, I have no doubt that it is the more correct.

"Ages. Of 47 Glasgow cases, in which the age is stated, 3 occurred betwixt 6 and 10 years of age; 13 between 10 and 20; 17 between 20 and 30; 5 between 30 and 40; and 9 between 40 and 50. The youngest was 6½, and the oldest 50. Of the 47 cases, 30, or about 64 per cent., occurred between 10 and 30. Of the recoveries, 5 took place between 19 and 30, and 1 was 45. Of 153 published cases, of which the age is stated, 12 occurred between 1 and 10; 43 between 10 and 20; 49 between 20 and 30; 21 between 30 and 40; 21 between 40 and 50; 5 between 50 and 60; and 2 between 60 and 70. Of the 153 cases, 92, or about 60 per cent., occurred between 10 and 30. The youngest was 22 months, and the eldest 70 years. While the above shows that tetanus may occur at any period between infancy and old age, it confirms the opinion, that it is a disease of youth and early adult life—upwards of 60 per cent. occurring in the decades between 10 and 30.

"Ratio of Mortality. Of the 50 traumatic Glasgow cases, 44 died, and 6 recovered, giving a ratio of 7½ deaths to 1 recovery. Of the 41 males, 37 died, and 4 recovered, being 9½ deaths to 1 recovery. Of the females, 7 died, and 2 recovered, giving 3½ deaths to 1 recovery. This table confirms the popular belief, that tetanus is less frequent and less fatal in females than males.

"Of the 171 published cases, 80 died and 91 recovered—144 were males, among whom the deaths and recoveries were all but equal (71 and 73)—27 were females, of whom two-thirds lived (9 died, and 18 recovered). On this point, this and all similar tables are most fallacious. The majority of these cases have been recorded because the patients lived; and the result is, that the recoveries exceed the deaths. In the Glasgow cases, all that could be found are recorded, and the result is 7½ deaths to 1 recovery. This I am certain is not beyond the truth; for while I have excluded all cases of chronic trismus, except one, I have included all the subacute cases of general tetanus. If I were to confine myself to the intensely acute forms of the disease, our table would prove it to be all but absolutely mortal. But such a method of calculation would be obviously unfair and fallacious. By statistics drawn up in this way, the ratio of mortality of all our severe acute diseases, as

typhus, small-pox, and pneumonia, would be greatly exaggerated. Of these diseases, the great majority of the intensely acute cases perish, while comparatively few of the subacute are lost; and were we to exclude the latter from our calculations, the ratio of mortality would be very high. In tetanus, as in them, the correct method is to include all well-marked subacute and acute cases. Unhappily, in tetanus the majority are 'intensely acute'; and I fear all such perish.

"An interesting question has frequently been asked, what proportion does tetanus bear to surgical lesions, especially recent injuries and operations? In order to answer this question, I have selected the year 1847, in which we obtained the fullest records of the cases in the hospital. These were five in number, of which four occurred after admission. From the report of that year, I find that, including operations, wounds, compound fractures, burns, etc., there occurred in the hospital 347* acute causes of tetanus, and 182† abscesses, ulcers, and other chronic causes of that disease. If we take four cases occurring within the hospital in one year, as a full average, which it certainly is, then one case of tetanus will occur in every 132½ cases of general surgical lesions. If we limit ourselves to the acute causes, the proportion will be one in 86½. Two of the cases were caused by burns, of which there were admitted 82, giving the high proportion of one in 41. Two followed lacerated wounds and compound fractures, of which there were admitted 124, giving the proportion of one in 62. Although these are merely approximations, yet I believe I am not far from the truth when I say, that one case of tetanus occurs in 150 cases of general surgical disease, accompanied with lesion of the surface, and one in 100 recent injuries and operations.

"Duration of the Disease. Of 41 fatal Glasgow cases, 18 died within two days; 7 in three days; 5 in four days; 2 in five days; 1 in six days; 3 in seven days; 1 in eight days; 3 in nine days; and 1 in ten days. The shortest period was in case 47, which proved fatal in twelve hours, after amputation of the thigh. Of the recoveries, the disease continued from twenty-five days the shortest, to forty-six the longest, period. It would thus appear, that of 41 fatal cases, 18 died before the third, and 32 before the sixth day; and that if a patient survive beyond that period, his chances of recovery are considerable.

"Period after Injury at which Symptoms of Tetanus occurred. Of 48 Glasgow cases, in which the time is stated, 1 occurred fourteen hours after amputation; 2 in two days; 1 in four days; 2 in five days; 4 in six days; 4 in seven days; 13 in eight days; 3 in nine days; 2 in ten days; 4 in eleven days; 5 in twelve days; 1 in thirteen days; 3 in fifteen days; 2 in sixteen days; and 1 in seventeen days. Of the cures, 1 was seized two days after the injury; the other five from the tenth to the sixteenth; 1 on each day except the fifteenth. Thus, previous to the tenth day, there were 30; and from the tenth to the seventeenth, there were 18 cases; showing that the large proportion of cases of tetanus (amounting to nearly 63 per cent.) occurred before the tenth day, and that these, with one doubtful exception, were fatal. Of the 18 occurring after the tenth day, 5, or about 28 per cent. recovered; thus confirming the pretty generally received opinion, that the earlier after the occurrence of the accident the symptoms of tetanus set in, the more certainly fatal is the disease likely to prove. Excluding the doubtful case (40), the Glasgow table stands thus:—29 cases occurring previous to tenth day of the injury, all fatal; of 18 subsequent to tenth day, 5 recovered.

"Situation of Injury. Of the 50 Glasgow cases, 8 were on the head, 7 on the trunk, 11 hands and fingers, 10 feet and toes, 2 arms, and 12 legs and thighs. The number of head injuries, followed by tetanus, is larger than is generally supposed; all were fatal. The hands and fingers, feet and toes, 21, confirm the opinion, that injuries of these parts rank among the most common causes of this disease. Of 169 published cases, 15 were on the head, 10 trunk, 43 hands and fingers, 47 feet and toes, 14 arms, 40 legs and thighs.

"The nature of the injury is shown by the following classified table:—

	Glasgow cases.	Published cases.
Severe injuries, bruises, compound fractures, etc.	17	70
Prick by nail, etc, generally on foot	6	31

* Operations less cases under other heads, 106. Wounds, including scalp, 70. Fractured skull, 4. Bites, 2. Burns, 82. Compound comminuted fracture, 50. Cut throat, 4. Gangrene, 15. Injuries and fistula of urethra and pudendum, 8. Onychia, 4. Peristitis, 5.
† Abscess, 30. Bed sores, 5. Open cancer, 10. Caries and necrosis, 20. Carbuncle, 3. Fistula not cut, 4. Ulcers, 110.

Wounds and slight lacerations of fingers and toes	10	..	17
Slight injuries	3	..	28
Amputations	2	..	8
Burns	0	..	4
Removal of mamma	1	..	0
Cupping on temples	0	..	1
Flogging	0	..	1
Laceration of cornea	0	..	1
Blow on back, etc.	0	..	5
Simple fracture of thigh	0	..	1
Fall on nose	0	..	1
Abortion	0	..	1
Retained placenta	0	..	1
Ligature of piles	0	..	1
Fistula ani	1	..	0
Extraction of tooth	1	..	1
Frost bite	0	..	1
Spontaneous gangrene of feet and legs	1	..	0
Scirrhus testis	0	..	1
Carious bone	1	..	0
Ulcers	1	..	2
	50		171

"From the above table, several interesting inferences may be drawn. (a) While tetanus may follow almost any form of surgical lesion, it is comparatively common after recent injury, and rare in connexion with the more chronic forms of disease. Of the latter, the Glasgow cases give us four examples, one each of fistula ani, spontaneous gangrene, carious tibia, and ulcer of the leg. But even of these, one only (caries of the tibia, which recovered) can be set down as chronic. The fistula was complicated with acute rheumatism, the gangrene was acute, demanding amputation of the leg, and the ulcer was inflamed and sloughing. (b) The more severe forms of injuries, consisting of compound fractures, and violent injuries of the hands and feet, supply the largest individual per centage, 17 out of 50, or 34 per cent. Next come wounds, and the slighter injuries of the fingers and toes. Pricks by nails, generally on the sole of the foot, give 6 in the Glasgow, and 31 in the published cases. Burns have been a fruitful and fatal source of the disease in our hospital, perhaps from their frequency and severity. In 1847, 1 in 41 of the burns died of tetanus. (c) In 5 cases, blows and sprains, without external lesion, seemed to induce the disease: of these, two died, and three recovered. (d) It had always appeared to me a peculiarity in tetanus, that while it would at times appear to be intimately connected with inclusion of a nerve in a ligature, it never followed deligation of navi, tumours, piles, or any disease in which this form of removal is employed. Of the numerous cases in which I have used the ligature in this way, and seen it applied by others, I have never met with one in which tetanus supervened. I began to think, that they were never conjoined; and must confess, I felt some disappointment when I fell in with one in which tetanus followed ligature of piles. It is published in *Dublin Medical Rep.*, vol. xxvii, p. 45. It proved fatal in twenty-four hours. (e) Tetanus is happily rare in obstetrical practice. The table contains only two examples,—one (122) from abortion, recorded in the *Monthly Journal of Medical Science*, 1850, p. 387, which proved fatal in three days; and one (164) from retained placenta, recorded in the *American Journal*, which terminated fatally on the first day. Others from abortion are recorded, but not with sufficient details to enable me to insert them in the table. Dr. Simpson (*loc. citat.*) says, that he met with a fatal case from the spontaneous detachment, by the uterus, of a 'large soft cellular polypus'.

"For the following case of tetanus after abortion, I am indebted to my friend Dr. Fleming.

"Mrs. McLean, aged 36, a healthy woman, was the mother of five children.

"June 10th, 1852. Seven days ago, being about three months pregnant, she miscarried without any assignable cause; and this was accompanied and followed by obstinate, but not very copious hæmorrhage. The discharge ceased to-day rather suddenly, and soon afterwards symptoms of trismus, supervened. Next day (the 17th), it was very complete, affecting the muscles of the neck, jaws, and face, the head during the paroxysm being bent forcibly backwards: at this time the muscles of the back were not affected. The eyes were sunken, and the expression anxious; the pulse was 80, small, but regular when free from paroxysm; deglutition was difficult; the bowels were constipated; the abdomen was full and tympanitic; there was no discharge

from the vagina. The tetanic symptoms steadily increased, the muscles of the back becoming severely implicated; opisthotonos was at times complete. The paroxysms, which at first recurred every thirty or forty minutes, soon increased in frequency and severity, and she died on the forenoon of the 19th. The treatment consisted at first of purgatives and turpentine enemata, which were followed by large and frequent doses of opium, free inhalation of chloroform, and friction over the neck and spine with chloroform. Latterly, beef-tea injections and brandy were administered. The vagina was frequently washed out by injecting tepid water.

"The uterus was about two and a half inches in length, and of corresponding breadth; it was quite empty and more flaccid than natural. When cut into, the muscular substance and lining membrane, particularly the latter, were very empty, so that the whole organ floated in a basin of water. There was no decomposition apparent.

"(f) Of tetanus following amputation, the Glasgow table gives two examples. Both operations were demanded on account of acute gangrene, and were both performed by me. I recollect a third case, the record of which has been lost, in which amputation was performed by one of my colleagues, for acute gangrene of the leg—the result was fatal. There have, doubtless, been others; but taking the cases as they stand, they give amputation as the cause of 4 per cent. of the cases of tetanus. The published cases give a close approximation, nearly 4½ per cent. One case followed extirpation of the mamma.

"(g) Among the published cases, there are five from blows without wound. Some of these are considered by their recorders as examples of idiopathic tetanus, but I think erroneously. There is ample proof that other lesions, besides those of the surface, induce the tetanic spasm, and the 'subcutaneous' may, I think, be correctly ranked among the number. The tables only give one case from simple fracture. It appears to have been comminuted, and a portion of bone to have penetrated the vastus internus. The Glasgow table affords no example of tetanus following a subcutaneous injury or simple fracture; and so far as my memory serves me, none have occurred during my connexion with the hospital; while, therefore, we admit the cause, we have ample proof of its rarity.

"State of the wound at the time of the occurrence of Tetanus. Of 5 Glasgow cases, which recovered, the wound was 'healing,' 'without discharge,' and granulating in 3; sloughing and unhealthy in 2. Of 32 fatal cases, the wound was said to be 'nearly healed and doing well' in 12; 'inflamed or suppurating' in 6; 'gangrenous and sloughing' in 14, and in one, at least, it must have been quite recent. In 15, therefore, it was healthy; in 22, inflamed or sloughing; and in 1, quite recent. Of 96 published cases, in which the state of the wound is mentioned, the following short table shows its condition:—

	Fatal.	Cured.	Total.
Healed or said to be healed	4	20	11
Healing	21	7	41
Inflamed or suppurating	8	14	22
Unhealthy, sloughing, gangrenous	12	10	22
	45	51	96

"To these must be added, 5 cases in which the wound must have been recent, the symptoms having set in from the fifth hour to the second day after its infliction.

"That a wound so recent as not to come under any of the four heads in the above table, can cause tetanus, can hardly, I think, be denied. No doubt, in the case of amputation, we have in many instances a previous injury, which may have been the cause of the tetanus, independently of the operation. But, admitting this, we have, I think, a sufficient number of authentic cases to prove, that a recent wound can induce tetanus. In case 155, the symptoms set in in four hours, and in 161, on the second day after 'a cut finger'.

"The two tables, taken together, show, that the inflamed and suppurating state is not the most common antecedent, and that it is less so than the unhealthy, sloughing, and gangrenous. The number of cases in which this last state of wound is recorded as present, or having existed, is very considerable.

"Next, perhaps, in point of interest to the 'green wound,' comes the perfectly 'healthy, healing, or healed'. If we take the two tables together, this state rather exceeds the preceding, precluding, I think, the possibility of doubting that tetanus very frequently occurs when the wound is perfectly healthy.

"Does it occur when the wound is quite cicatrised? Of our Glasgow cases afford no unequivocal example. The ne

approach to it, perhaps, is case 13, in which the sole of the foot was pricked by a nail on the 16th July—tetanus set in on the 26th, and it is stated that the wound 'had not suppured'. But this is by far too equivocal to enable us to say that the prick had quite healed in ten days. In every other case, the wound was more or less open; and in my own experience, I have never seen tetanus supervene upon a 'healed' wound. Of the published cases, 11 are said to be 'healed'; and this, added to the high authority of Larrey, Dupuytren, Travers, Curling, and I believe many others, would appear amply sufficient to establish the fact. Still, I confess, it is one regarding which I entertain considerable doubt. The length to which this communication has already extended, forbids my entering on a detailed investigation of this point. So far, however, as I have carried it, the following quotation from Mr. Travers conveys the conclusion at which I have arrived: 'Not unfrequently the punctured wound, as from a nail, wears the aspect of being healed, and is almost forgotten, when the spasms set in.' I suspect that, though they 'wear the aspect', they are not healed."

Dr. Lawrie has reserved his analysis of the treatment and of other points to a future number of the *Glasgow Journal*. When his observations are published, we shall notice them.

TREATMENT OF VARICOSE VEINS BY NEEDLES AND LIGATURES.

Dr. J. C. BUTLER, of Dunham, Canada East, relates the following case in the *Canada Medical Journal* for February 1853.

Mr. F. C., aged 23, of a scrofulous diathesis, consulted Dr. Butler, on 30th July last, for varicose veins of the left leg. The patient said that this condition had been produced by over muscular exertion made several years previously, from which time it had constantly increased, accompanied by occasional obstinate ulcerations. The internal and external saphena veins, with their branches, presented the appearance of a complete mesh-work of diseased veins; also, on placing the thumb upon the principal vein above the knee, the patient being in the recumbent posture, and on removing the compression suddenly, while he was in the erect position, a sensible regurgitation of its contents was apparent, producing a disagreeable sensation to the patient.

On September 2nd, Dr. Butler performed the following operation. Common brass pins were introduced behind the veins; strong waxed ligatures were then passed tightly round the pins so as to include a portion of the integument and a fold of the veins to induce sloughing of the circumscribed parts. Thirteen pins were thus applied to different portions of the veins below the knee, and one to the common saphena, a few inches above it. Quietude and light diet were enjoined. On the fifth day after the operation, there was no constitutional disturbance, and but little swelling of the foot and leg. New ligatures were applied.

Sept. 8th. The patient had suffered much pain during the previous night. The foot and leg were more swollen. Dr. Butler ordered the limb to be elevated, lead lotion to be applied, and ten grains of Dover's powder to be taken at night, and a black draught in the morning.

Sept. 11th. There was sloughing of the strangulated parts. The ligature was tightened, and the Dover's powder was ordered to be repeated.

Sept. 15th. Several of the pins were removed by ulceration.

Sept. 25th. The pins were all removed, and the ulcers appeared healthy.

Oct. 7th. The ulcers were all healed, and the appearance of the leg was much improved. A ligature was applied to a large vein passing over the internal malleolus.

Oct. 14th. The patient had walked a mile on the previous day, and was seized with cold chills, followed by pain in the head, and pain and swelling in leg. He was bled from the arm, the leg was elevated, and cold water was applied. Ten grains of Dover's powder, with six grains of calomel, were given every eight hours.

Oct. 15th. The patient had rested quietly. There was redness and extreme sensibility along the internal saphena as far as the knee. A blister was applied from the foot to the knee, over the vein, and the powders were repeated.

After this time the patient improved, and became rapidly convalescent.

NEW METHOD OF PLUGGING THE NOSTRILS IN EPISTAXIS.

In the *Revue Médico-Chirurgicale*, for October 1853, Dr. A. LÉYDET, of Gardannex, describes an instrument which he has

contrived for plugging the nostrils in cases of epistaxis, especially in children. The apparatus consists of a gum-elastic sound, to which is applied a bladder. This can be introduced and inflated; the air is retained by a stop-cock; and the inflated bladder thereby is made to act as a plug and to restrain the hæmorrhage.

PRACTICE OF MEDICINE AND PATHOLOGY.

NON-RECURRENCE OF DYSENTERY.

In a Clinical Report on Dysentery, based on an analysis of forty-nine cases, and published in the *Buffalo Medical Journal*, Professor FLINT makes the following observations. We copy them from the *New York Journal of Medicine* for September 1853.

He proposes the following questions as interesting in themselves, and important in their pathological bearings. What remote effects, if any, in the organism, follow an attack of dysentery? Does it impair the constitutional vigour? Is the patient afterwards liable to renewed attacks of the disease, or is the susceptibility to the action of the cause, or causes, lessened or destroyed, so that, the morbid process having once taken place, there is greater security, if not entire exemption thereafter?

His facts, he says, are few, but they point to something more than coincidences—they point to laws of the disease which do not appear as yet to have received attention.

"Of the thirty-eight cases ending in recovery, in sixteen the patients either continued under observation, or definite information was obtained respecting their subsequent health for periods varying from one year to thirteen years. To be more precise, with regard to these periods, the duration of the subsequent history in the cases respectively, are as follows:—thirteen years, one case; seven years, two cases; five years, two cases; four years, nine cases; two years, one case; and one year, one case. In all, there were sixteen cases. Of these sixteen patients, only one has died. This patient died with tuberculosis of the lungs four years after recovering from dysentery. Of the remaining fifteen cases, in all the health has been good during the periods respectively during which the patients remained under observation, or within knowledge. I mean by this, that not one has suffered from any other important disease, and in nearly every instance there has been excellent health.

"Not one of these fifteen patients has experienced a second attack of dysentery. The result is rendered somewhat more striking by the fact that, exclusive of the case in which the date of the disease was but a year since, all the patients have been for several years past within the sphere of an epidemic influence, the disease, as already stated, having prevailed more or less, as an epidemic, in this city, in the autumnal months for the last four years. I can also call to mind several cases of dysentery occurring at least four years since, the histories of which were not taken, the patients, in the mean time, being under observation. In none of these instances has the disease been twice experienced. I have not yet met with a second attack of dysentery. It is worthy of notice that three of the cases in this collection occurred in one family at different dates,—viz., one case, thirteen years ago; one, four years; and one, two years. In these instances new subjects were attacked, they escaping who had previously had the disease.

"It would seem, from these facts, that an attack of dysentery does not exert an unfavourable influence on the organism, that patients are not rendered thereby prone to any particular disease, but, on the other hand, enjoy good health. It would also seem that patients are not liable to a repetition of the disease.

"I would not be understood as presenting these inferences in the light of established truths. The number of observations is too small to warrant deductions which shall represent fixed laws of the disease. But, as already remarked, it is difficult to account for the facts, on the hypothesis of their being due to mere coincidence; and I repeat, that the facts point to the existence of laws which remain to be settled by further investigation. We are at least justified in concluding, from the data before us, that deterioration of the health subsequent to dysentery is not the general rule, and that an attack does not lead to any increased susceptibility to the cause or causes of the disease."

REPORTS OF SOCIETIES.

EPIDEMIOLOGICAL SOCIETY.

MONDAY, NOVEMBER 7TH, 1853.

BENJAMIN G. BABINGTON, M.D., President, in the Chair.

The first meeting of the fourth session of this Society was held at the house of the Royal Medical and Chirurgical Society, 53 Berners Street, on Monday, the 7th instant.

Sir JAMES McGRIGOR, who retires from the office of Vice-President, was elected an honorary member.

PRESIDENT'S ADDRESS.

The PRESIDENT congratulated the members upon being again assembled for the purpose of inaugurating another session of the Epidemiological Society—a society which, although only just entering upon the fourth year of its existence, has already borne evidence of healthful and vigorous growth, and given ample promise of yielding rich harvests during future years.

After some general remarks, he read the following list of papers read at the monthly meetings during the past session:—

November 1st, 1852. Epidemic Suetie Miliare of the Herault. By Dr. Swaine of Scarborough. (Read by Dr. Babington.)

December 6th, 1852. Climate of the Hill Stations in India. Second Part. By Frederick Corbyn, of the Bengal Army. (Communicated by Col. Sykes.)

January 3rd, 1853. The Relation of Vaccination and Inoculation to Small-Pox. By Dr. Waller Lewis.

February 7th, 1853. The Influence of Noxious Effluvia on the Origin and Propagation of Epidemic Diseases. By R. D. Grainger, Esq. [This paper was published in the ASSOCIATION JOURNAL for February 25th and March 4th.]

March 7th. Facts relating to Scarlet Fever. By B. W. Richardson, Esq. [This paper was published in the ASSOCIATION JOURNAL for June 10th.]

Observations on Sore Throats, and their Relation to Scarlet Fever. By J. Bower Harrison, Esq.

April 4th. Epidemic Small-Pox in Calcutta. By Dr. Finch. May 2nd. Comparative Mortality of Large Towns and Rural Districts. By Dr. Snow.

June 6th. On Quarantine; being a sketch of the most striking results of Quarantine in British Ports since the beginning of the present Century. By Dr. Milroy. [This paper was published in the ASSOCIATION JOURNAL for July 8 and 22.]

July 4th. On Yellow Fever; comprising the History of that Disease as it appeared in the Island of Antigua in the years 1835, 1839, and 1843. By Dr. T. Nicholson, of Antigua. [This paper was published in the ASSOCIATION JOURNAL for September 16th.]

August 1st. Contagion and Infection, in Relation to Epidemic Diseases. By John Grove, Esq.

As cholera has unhappily reappeared in this country, papers on points connected with that disease will be especially acceptable. Our Society will be the most legitimate medium through which to bring such communications before the profession.

Circumstances have arisen within the last six months which have called forth unwonted exertion on the part of two of our Committees—the Committee on Small-Pox and Vaccination, and the Committee on Cholera. During the last session of Parliament, Lord Lyttelton succeeded in obtaining the sanction of the legislature to a bill for rendering vaccination compulsory in this country. During the progress of the bill, the assistance and suggestions of the committee were requested by the government, and deputations, on several occasions, had conferences with Lord Palmerston, Lord Lyttelton, and other Ministers of the Crown. It is also to the Society a source of gratulation and pride, that the first part of the Report on Small-Pox and Vaccination (the first fruits of the Society) has been printed at the expense of the government, and, in the form of a Blue Book, has been presented, by order of Her Majesty, to the members of both Houses of Parliament. A copy of the report has also been forwarded to each member of the Society.

The Cholera Committee appointed last year has been engaged in drawing up a comprehensive series of queries, with the view to obtain the most ample information regarding this mysterious disease. The queries have been completed, and are now in the hands of the printer. It is intended by the Committee that they shall have extensive circulation abroad, as well as at home; and here I cannot help observing how important it would have been

to the inquiries of the Cholera Committee, had the resources of the Society admitted of the simultaneous and unrestricted operation of the Committee appointed to investigate the Diseases that affect the Vegetable Kingdom.

Let us hope that the universal importance, and the benefits likely to follow from the labours of these committees, will excite sympathy in those quarters where effective aid can easily be rendered, so as to enable them and the other committees to prosecute their inquiries with that freedom which is most likely to insure success.

Our best thanks are due to the Right Hon. the Earl of Clarendon, for a renewal of the permission to our secretaries to inspect despatches and other documents bearing on cholera, first granted through the courtesy of his lordship's predecessor in office, the Right Hon. the Earl of Malmesbury. We are also under deep obligations to the Poor Law Board, the General Board of Health, the Registrar-General, and other government authorities, for access to public documents, readily accorded to the members of the various committees.

On former occasions, it had been his (the President's) privilege to open the session with an introductory address. This evening, however, this honourable and important duty devolved upon an excellent and able colleague—Dr. James Bird.

LAWS OF EPIDEMIC AND CONTAGIOUS DISEASES.

BY JAMES BIRD, M.D.

Dr. BIRD, after bestowing a well merited compliment upon Dr. Babington, addressed the meeting on the surpassing utility of those scientific investigations which are the objects of the Epidemiological Society's research. Fully appreciating the extent and importance of preventive medicine, as the mistress rather than the handmaid of curative science; and having been anticipated in all that regarded the general objects of the Society by the President's former addresses, he had selected a special subject, "The Laws of Epidemic and Contagious Diseases"—a subject which might, he thought, be of interest while we now stand on the threshold of an expected outbreak of cholera.

The inquiry divided itself into, 1st. The laws under which epidemic and contagious diseases take their origin, and are diffused. 2nd. The application of a knowledge of these laws to prevent predisposition to such maladies, mitigate their severity, and limit their diffusion. Both were subjects of necessary study for the profession and the people, in order that the intellectual masses of the latter might learn the true philosophy of health and disease, and know when to avoid the meddlesome interference of the bold and fearless empiric, or cease to trust, when nature's resources must fail, the do-nothing practice of the homœopathist. More comprehensive principles and practical rules for preventive medicine were yet requisite; and, in all attempts to investigate the nature and character of epidemic and contagious disease, the observations and opinions of past ages should not be neglected. The characters of epidemic and contagious diseases, including small-pox, measles, whooping-cough, scarlet fever, typhus, plague, yellow fever, and Asiatic cholera, were then given; and their geographical distribution, with their modifications of character, pointed out on a copy of Sir George Ballingall's map of these varied affections. After having described the various conditions under which these diseases originate, are propagated, and decline, Dr. Bird asked whether we could obtain a scientific expression of the nature of the phenomena, and facts regarding them, which might be applicable as sanitary rules of practice in preventive medicine? and having done so, he embodied these phenomena under four different laws, specifying, in his subsequent remarks, the various exceptions which might occur under each. Since cholera and other epidemic diseases would be active, he said, in proportion as the accessory circumstances which favour their origin and diffusion were allowed to remain without a remedy, it was the duty of every wise and paternal government to use its strenuous efforts for the removal of all such. The market sale of improper articles of diet, or meat in a state of decomposition, was to be prevented; good and untainted water ought to be supplied for the population; houses of refuge, or soup-kitchens, established for the poor, and their dwellings ventilated, white-washed, and kept clean; the surface drainage and sewerage of neighbourhoods were to be improved. Finally, he recommended, as a wise precaution in cholera, that no more intercourse between the sick and others should be allowed than might be necessary for comfort, nursing, and proper medical treatment.

The address was listened to with much attention, and warmly received.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, NOVEMBER 3RD, 1853.

RICHARD QUAIN, M.D., President, in the Chair.

PRESIDENT'S ADDRESS.

Dr. QUAIN chose as his subject, "The Advancement of Medical Knowledge". He dwelt on the relative influence which observation and the exercise of the intellectual faculties have on this object. He showed that, on the one hand, mere observations and the collections of facts tended to isolate pathological phenomena, and rather to retard than advance knowledge; whilst, on the other hand, the exercise of reason in the investigation of facts was the principal source whence had proceeded all the great scientific discoveries which had placed human knowledge in its present advanced position. Dr. Quain further showed how materially organic chemistry, physiology, and those branches of physics which treat of light and sound, contributed to our knowledge. He dwelt on the value of societies constituted like the Harveian in collecting and rendering traditional the experience which every day falls to the lot of the busy practitioner, but which, if unwritten, is for ever lost; and concluded by a kindly exhortation to friendship, good feeling, and unity, in the great object of our profession—the mitigation of human suffering.

Dr. Quain's address was listened to with much attention by a full assembly of members. This was the first meeting of the session.

NORTH LONDON MEDICAL SOCIETY.

WEDNESDAY, OCTOBER 12.

RICHARD QUAIN, Esq., F.R.S., President, in the Chair.

PRESIDENT'S ADDRESS.

Mr. QUAIN, in taking the Presidential Chair at the first meeting of this Society, delivered a very instructive address, which has been published. He compared the state of medicine and of medical instruction as it existed a quarter of a century ago, with the improved aids to diagnosis and treatment, and the increased and more convenient opportunities of acquiring knowledge, which are met with in the present day. He also referred to the advantage of societies as a means of keeping pace with the progress of the times.

VEGETABLE PARASITES ON THE HUMAN BODY. BY W. JENNER, M.D.

Dr. JENNER's paper was illustrated by the exhibition of specimens under the microscope. This paper has been published.

WEDNESDAY, NOVEMBER 9.

RICHARD QUAIN, Esq., F.R.S., President, in the Chair.

CASE OF OSTEIOD CANCER. BY W. SEDGWICK, ESQ.

After a review of the history and pathology of osteoid cancer, which, Mr. SEDGWICK stated, had apparently escaped the notice of pathologists, until Müller, in 1843, published a memoir on the subject, accompanied with descriptions of several cases, he commented on the reasons for considering the disease as cancer, and was of opinion that they were fully confirmed by the case which he had recently had an opportunity of observing. He drew attention to the opposite view entertained on this point by Lebert, who had included "osteoids" in the list of benign tumours. After alluding to Mr. Stanley's observations on the disease, and to those in Mr. Paget's recently published *Lectures on Surgical Pathology*, Mr. Sedgwick gave a very full description of the case, which was illustrated with preparations of all the parts affected with the disease.

The subject was a young man, aged 19, formerly a patient in University College Hospital under Mr. Quain, who had amputated the left thigh for an osteoid tumour affecting the lower end of the femur. After remaining free from the disease for nearly three years, the patient's chest became affected (in consequence of taking cold); he spat a little blood during the first two or three days, and had a troublesome cough. Some weeks after appearance of disease in the chest, he came under the notice of Mr. Sedgwick, who diagnosed cancer affecting nearly the whole of the left lung, a small portion only, towards the apex, being free. A tumour was after some time noticed in the right clavicle, and considered to be cancer. After an abstract from his notes of the case during a period of five months, Mr. Sedgwick continued to relate that a few weeks before death, symptoms of the head being affected showed themselves, ending in convulsive attacks of the right side of the body, which continued to appear at intervals till death.

On examination of the body, an osteoid tumour of the size of the fist was found in the posterior mediastinum; and a similar tumour, of larger size, in the right side of the chest. Three or four small tumours, some of them unossified, were found near

the base of the right lung: the tissue of this lung was healthy. The left lung was riddled with cavities, containing purulent matter; the thoracic aorta, for more than three inches, was surrounded by a firm cancerous mass, which on section presented centres of ossification: a portion of a similar mass was found in the vena cava; and the left bronchus was completely blocked up by a partly calcareous mass. A medullary tumour was found in the left hemisphere of the brain. The abdominal and pelvic viscera were healthy.

Mr. Sedgwick adverted to this case as presenting a good illustration of what usually occurs in well marked osteoid cancer; namely, its primary appearance at an early age in the femur, and its subsequent development in the cavity of the thorax. The connexion between osteoid and medullary cancer was to be noticed. After some observations on the development of osteoid tumours, Mr. Sedgwick concluded by remarking on the generally rapid progress of the disease, in which respect the case under notice was an exception, and might be looked upon as an encouraging instance of the success which may occasionally attend an operation for the removal of the primary disease.

The PRESIDENT stated that, as the case had been under his care at an early period, he would call attention to a few of the leading practical points connected with it. When he saw the patient, there was excessive pain, and the glands of the groin were swollen and very tender: but he came to the conclusion that they were affected, not with the specific disease, but inflamed from the effect of the blistering which had been applied before the patient was brought to the hospital. The result proved the correctness of this view, for the pain and swelling in the glands gradually subsided after the operation. The case well illustrated the advantage which may result from an operation for cancer, and at the same time defined the limits of its advantage. The operation did not remove the whole disease, for the disease was a general one, and pervaded the system; it was, in fact, in the blood. But the operation removed the source of pain and distress, of which the patient would have died speedily. It was productive of further benefit; for the local disease becomes in its turn a new source of contamination to the system by absorption; and this additional constitutional taint, which would have resulted, was prevented. In this case, the new deposit which formed in the chest and elsewhere in the upper part of the body, had no connexion with the disease removed from the lower limb.

DISEASE OF THE EAR EXTENDING TO THE BRAIN.

BY JAMES PART, ESQ.

Mr. PART related the case of a clergyman, aged 25, who for a period of five years had suffered from a purulent discharge from the right ear, attended occasionally with great pain. The disease proved fatal suddenly, without the extent of the mischief having been suspected.

The patient, born in India of English parents, came to England when eight years of age. He had always been well fed and clothed, and had never been subjected to mercurial treatment; he had lived a very regular life. He had lost a brother and sister from scrofulous diseases. About five years before his death, after taking cold, and having about the same time two severe falls on his head, he was attacked with acute pain in the ear, followed by a copious, offensive, puriform discharge from the meatus, accompanied by a loss of hearing. He consulted several eminent aurists for this affection, but did not derive any benefit from the treatment recommended. In the summer of 1849, he consulted Mr. Pilcher, who pronounced the case to be acute otitis, with fungus of the right meatus. Under the care of this gentleman, he improved considerably in health, but was constantly taking cold and suffering from a recurrence of his symptoms. He then became subject to fits of giddiness, in which he usually fell down. These were succeeded by vomiting, and great pain in the ear and head. A year since, two small glands behind the ear began to enlarge, and ultimately suppurated; leaving fistulous openings, which discharged freely at times when the flow from the ear diminished, and increased when the latter subsided. He was now compelled to give up his clerical duties. During the last year, he had taken sarsaparilla and iodine. When Mr. Part first saw the patient (July 19, 1852), he was suffering from severe pain in the head, greatest at the back, vomiting, inability to move without excessive pain; he could only lie with the head horizontal to the body. The countenance was heavy, and not symmetrical; he had partial ptosis and turning up of the eyeballs, slight squinting, and the right angle of the mouth was drawn up. There was a swelling in front of the right ear, extending nearly to the margin of the orbit, great tenderness of the concha, with copious puriform discharge from

the external meatus. Behind this were two fistulous openings, communicating with each other. The skin was cool, except on the forehead, which was very hot; the hands and feet were cool; the pulse 68, full; the tongue was coated, protruded towards the right side; he had considerable thirst; his bowels had been constipated for three days; the urine was scanty and high coloured, and he had hesitation in passing it. He answered questions slowly and imperfectly; his manner was strange, morose, and inconsistent. By acting on the bowels freely, and the administration of saline diaphoretics, a certain amount of amendment was obtained, which continued up to the 25th, six days from the time when he was first seen by Mr. Part. As he had passed restless nights, suffering great pain, muriate of morphia was administered at night, which secured him sleep. On the 23rd, as he was suffering intense pain, a large blister was applied to the nape of the neck, which gave great relief to the pain in the head. From the 25th the patient gradually became worse, and grew restless, continually desiring to change his room; his speech and deglutition became more and more impaired; he had difficulty in micturating, and at last complete retention, requiring the introduction of the catheter. The swelling in front of the ear having increased in size, an opening was made into it by the late Mr. Bransby Cooper, who was called in with Dr. Babington; but only a small quantity of pus was evacuated. The pain increased; the tongue became more coated; he was now roused with difficulty; he could not be moved, and the evacuations were passed involuntarily in bed. On the 2nd of August, slight tetanic symptoms set in; the erector muscles of the spine assumed a state of opisthotonos; and he died on the morning of the 3rd, at 4 A.M.

Examination of the Body, eight hours after death. On cutting through the integuments over the swelling in front of the ear, a cavity as large as a hazel nut was met with; and, communicating with this, was another, beneath the temporal muscle, as large as a walnut. Both were filled with a soft cheesy substance. A probe passed into this first cavity struck against the dura mater lining the squamous bone. On opening the head, the dura mater was found greatly injected outside and pink within, and was adherent over the whole surface of the temporal bone, but thickened in the right middle lateral fossa. When this membrane was removed, the whole of the petrous bone, the basilar process of the bicipital, as far back as the posterior third of the foramen ovale, and the large wing of the sphenoid, extending inwards to the middle line of the skull, were ascertained to be degenerated into a soft cheesy mass, similar to that contained in the above mentioned cavities. A probe entering the opening behind the ear passed easily till it appeared in the foramen ovale; and another, introduced into the meatus, appeared through the petrous bone. The malar bone was entirely destroyed, and the mastoid process of the temporal completely occupied by disease. The ventricles contained three ounces of bloody serum; the arachnoid was much injected, and between it and the pia mater was a layer of very yellow pus, extending along the base of the brain; it was greatest in quantity on the anterior surface of the medulla oblongata, down the front of the medulla spinalis as far as the view could be obtained. In the middle lobe of the brain was an abscess containing upwards of an ounce of very fetid greenish pus; and a second abscess existed in the middle of the posterior lobe, containing a similar kind of pus. The section of the cerebral substance presented an unusual number of bloody points. No similar deposit was found elsewhere in the body.

Mr. Part alluded to a paper by Mr. Toynbee, read before the Medico-Chirurgical Society in 1851, recording forty-one cases of fatal cerebral disease, originating in disease of the tympanic cavity, in most of which discharge from the external meatus had for many years been almost the only symptom. He made an analysis of the symptoms and morbid states found in those cases, comparing them with those in the case under notice, and concluded, by calling attention to the importance of attending to cases of this description in the early stage, when the discharge, often unattended with pain, is the only symptom which the surgeon or physician has to guide him.

This case elicited an animated discussion.

MEDICAL SOCIETY OF LONDON.

SATURDAY, NOVEMBER 5TH, 1863.

JOHN SNOW, M.D., Vice-President, in the Chair.

PATHOLOGY AND TREATMENT OF CHOLERA. By JOHN ROSE CORMACK, M.D. [Dr. Cormack's paper, which was read only in abstract, is published in the *ASSOCIATION JOURNAL* of last week.]

Mr. Ross recommended nitrate of silver as an astringent in cholera. He had used it in about eighty cases towards the close of the last epidemic. [Vide *Medical Times*, 15th Sept. 1849.] Mr. Ross was inclined to think that cholera is, as the author had argued, similar to an intermittent fever.

Mr. DENDY thought that the paper contained the most judicious observations on cholera which he had ever listened to or read. He differed, however, from the author regarding the pathology and treatment of the disease. [Laughter.] He meant to say that in some points he disagreed with Dr. Cormack. He considered cholera and intermittent fever to be analogous diseases; but he could not believe it to be correct to regard diarrhoea and cholera as identical, or as stages of the same disease. He objected to external heat. Patients had sometimes been boiled and baked to death. He (Mr. Dendy) usually directed the body to be first washed with vinegar and water, then with salt and water, and well rubbed to induce warmth, after which flannel wrappings were used. He directed the doors and windows to be kept open to promote the free inspiration of oxygen. It had been said that in some of the worst cases of cholera, in which the patients were knocked down blue, there was no serous flux. There might, he admitted, be no external flux; but in such cases the serous fluid was always to be found in the stomach and intestines, particularly in the colon.

Mr. R. R. ROBINSON agreed with the author as to bad cases getting well when recovery could not be ascribed to the special treatment which had been adopted. But the question was in what proportion do such recoveries take place, and in what ratio are the recoveries increased under particular modes of treatment. He thought that the treatment recommended by the author was generally judicious; but it was a great error, he conceived, to disparage the calomel plan, which, he believed, had been more successful than any other. There were three causes from which cholera patients were principally lost; viz. the collapse or direct action of the poison, exertion when too feeble to bear it, and spasm. He quite agreed with the author that many persons suffered from the cholera poison who did not present any of those symptoms which were usually regarded as diagnostic of cholera.

Dr. CRISP said that cholera first appeared in 1817. He had, like the author, studied the literature of the subject; but he had arrived at different conclusions. He (Dr. Crisp) maintained that cholera was a new disease, *sui generis*, and that it had no analogy to ague, either in its symptoms or topography. Little information, he thought, was likely to be obtained by the system of observation by district societies advocated in the paper. Certain plans of treatment ought to be tried in hospitals, by a commission under government. He would suggest that three appropriate wards be set apart in one or more of our hospitals, and three modes of treatment be steadily carried out in each hospital, under competent direction and observation.

Dr. WEBSTER agreed with nearly everything which had been advanced by the author. He thought that Dr. Crisp's objections to the ague doctrine were quite untenable; and among other facts he mentioned that ague was often confined to one side of the Tiber, and prevailed on one side of a street in Rome, when there was not a case upon the other side. Dr. Webster then referred to various historical facts and to the writings of the older physicians, to show that cholera was not a new disease.

Mr. HENRY LEE spoke of the transfusion of blood and the use of injections into the circulatory system in cholera. He thought that the fluid ought to be introduced by an artery rather than by a vein; and he had fully made up his mind to select the radial artery, should he be called upon to introduce blood or any medicinal fluid into the circulation of a cholera patient.

Dr. SIBSON inquired upon what grounds Mr. H. Lee preferred an artery to a vein?

Mr. H. LEE replied that, from the capillaries intervening, no danger could arise from the air which might unintentionally be thrown in along with the fluid. From numerous experiments upon animals, he was convinced that almost any quantity of blood might be safely thrown into the system by the radial artery.

Dr. CORMACK said that time would not allow him to discuss the calomel treatment of Dr. Ayre with Mr. Robinson. There was, however, he thought, no conclusive evidence in its favour, and he inclined to think that there was proof of inordinate doses of calomel exhibited during collapse, having proved poisonous during early convalescence. Not having had any experience of Dr. Ayre's method, he (Dr. Cormack) had not spoken of it in his paper, in which he had, after all, such a superfluity of topics as obliged him to condense exceedingly. The objections of Dr. Crisp had, he (Dr. Cormack) thought, been answered by Dr. Webster. Dr. Cormack referred to the prevalence of

neuralgic affections, with a well marked periodic type, as having, in his experience, characterised the rise and decline of the last cholera outbreak, and as having abounded some weeks ago, when cases of serous diarrhoea were not uncommon.

NORTH STAFFORDSHIRE MEDICAL SOCIETY.

This Society held its first anniversary meeting on the 10th instant, at the Athenæum Rooms, Stoke-upon-Trent. It already numbers twenty-five members, and during the year has held four meetings. The objects contemplated at the formation of the Society, viz., to afford means of friendly intercourse between the medical practitioners of the district, improvement in medical science by the reading of papers, the detail of cases, and discussions thereon, and the protection of their general interests by endeavours to suppress the evils resulting from the practice of unqualified persons, have all been carried out to a satisfactory extent.

The meeting was well attended, most of the leading medical men of the Potteries and Newcastle being present.

Dr. Wilson delivered an able and interesting address, on his retirement from office as President.

The following gentlemen were chosen officers for the present year:—*President*: Robert Garner, Esq., Stoke-upon-Trent. *Vice-President*: S. P. Goddard, Esq., Longton. *Treasurer*: B. Boothroyd, Esq., Hanley. *Secretary*: Joseph Walker, Esq., Burslem.

Several morbid specimens and some surgical instruments were exhibited.

A letter from Dr. Charlton, of Newcastle-upon-Tyne, relating to the recent outbreak of epidemic cholera in that district, was read.

It is intended to hold a special meeting for the consideration of Epidemic Cholera, on the 24th instant, to which medical men who may not be members of the Society are invited.

ASSOCIATION INTELLIGENCE.

MEDICAL BENEVOLENT FUND.

At the last monthly meeting of the Committee in October, the Treasurer reported that since July 1st, the sum of 187:15:6 had been received in subscriptions, and £38 in donations; the expenses had been £125:16:8; the sum now in the hands of the Treasurer being £12.

The Treasurer also reported that there were vacancies for two annuitants of £15 each. These vacancies were filled up by the election of a surgeon, aged 73, who is in great distress, and in bad health; and of the widow of a medical man, aged 63, who is entirely dependent upon her children, of whom one is a cripple.

The number of annuitants at the present time is eight, of whom six are in the receipt of £15 each, and two of £20 each.

The following cases have been relieved:—

I. The widow of a medical assistant, to whom the Treasurer had advanced two guineas, to assist her in entering upon a situation. Voted £2:2.

II. An Irish medical student, now in London, the son of a medical man: his health is so impaired that he cannot follow any avocation, and he is in distressed circumstances. Recommended by Sir Jas. Clark and Dr. Forbes Winslow. Voted £5.

III. The wife of a surgeon who went to Australia five years ago, and has not since been heard of. He left his wife and four children, who have endeavoured to support themselves, but they are now in great distress. Recommended by Mr. Ince, Dr. Inman, and Dr. Hall of Hounslow. Voted £10.

IV. The wife of a medical man residing at Birmingham; has several children to support, and near her confinement. Husband intemperate, and earns nothing. Relieved several times previously. Recommended by Dr. Russell, of Birmingham. Voted £5, to be placed in Dr. Russell's hands.

V. The daughter of a medical man in great distress. Voted £5.

VI. A surgeon lately residing in Bath, where for seven years he had endeavoured unsuccessfully to make a practice. Has a wife and six children, and is anxious to emigrate. Recommended by Mr. Norman, Mr. Soden, Mr. George, and Mr. Barrett. Voted £10, to be devoted to the purposes of emigration.

VII. A practitioner in the east end of London, who has been in practice for forty years. He has a wife and three children dependent upon him, and the income from his practice is not

more than £90 a year; he is now suffering from ill health. Recommended by Dr. Ramsbotham, Dr. Cobb, and Mr. Self. Voted £10.

VIII. A medical assistant with a large family in very straitened circumstances; relieved on several previous occasions. Voted £5, to be placed in the hands of Mr. Bacet.

EDITOR'S LETTER BOX.

MILITIA SURGEONS.

LETTER TO THE EDITOR.

SIR,—The ASSOCIATION JOURNAL, devoted as it is to the interests of the general body of Practitioners, will not, I believe, be thought to be improperly intruded upon, if a portion of its pages be allowed for a short consideration of the present state of Militia Surgeons.

Previous to the year 1829, the surgeons of militia were upon the permanent staff, receiving permanent pay, of, I believe, 6s. a day; subsequently to the year 1829 this was discontinued, as in fact were the permanent staffs, with the exception of the adjutant, and perhaps a sergeant or two in each regiment.

Upon the reëmbodiment of the militia in 1852, the surgeon was again made one of the staff, but only received pay for the month of training. By the recent orders of July 1853, the surgeon is to attend all the staff (including of course the adjutant); their wives and families, at twopence per head per week, throughout the year.

The militia of England is presumed to be officered by men of independent means, country gentlemen, or others, on whom the duty very properly devolves of devoting a portion of their time to the purpose of training a body of men, who in case of need should assist in the defence of the country, and with whom, if necessary, they would take the field.

After the monthly training, unless a necessity arises, these officers have no further duty for that year.

There are, however, duties of a more permanent character, and those performing them are placed upon the staff with permanent pay. Now the surgeon's duty is continuous, and extends throughout the year: he has to examine the men that are constantly required to fill up vacancies, and to attend the staff, composed of middle aged men (who from their previous services and habits are liable to disease), as well as their wives and children. This necessitates permanent residence and permanent duties.

Why has he not permanent pay? Next year, we are told, some of the regiments are to go into barracks, or camps, as was the case this year with the East Suffolk, when an absence of some weeks from the surgeon's ordinary professional occupations must occur.

The way, in fact, that the medical officers of the militia have been treated, is only another instance of the exaction of duties from the profession without any adequate reward. The appointment is, in effect, an honorary one; the surgeon is ingeniously placed in the same category as the country gentleman, only that with the one the duty is temporary, with the other continual, for the twopence per head per week is simply ridiculous.

Why, you will say, are these appointments retained? Because a feeling prevails that the surgeon must before long be placed upon permanent pay. But I can assure these sanguine individuals, that upon a memorial on this subject being lately presented to the Home Secretary, by one of our body, an answer was returned that it was not the present intention of the Government to do so, and that it was the *first complaint* they had heard on the subject: and the inference evidently drawn (very agreeable to official quietude) was, that our *silence* gave *consent* to the present state of things.

The only way to act in a matter of this kind is by a collective memorial; and to effect this, a meeting of militia surgeons should be held in London. I may, however, trouble you again upon this subject. I am, etc.,

A MILITIA SURGEON
AND MEMBER OF THE ASSOCIATION.

November 11th, 1853.

METEOROLOGY.

LETTER FROM T. HERBERT BARKER, M.D., TO THE EDITOR.

SIR,—It is solely for the purpose of pointing out a few incoherencies and contradictions, which might possibly mislead some of your readers, that I venture to make a few observations

upon Dr. Burder's letter on Medical Meteorology in your last number. That gentleman writes that it is "important that investigations on this branch of science should be conducted upon sound principles, lest valuable time be wasted upon fruitless researches, and the progress of knowledge retarded by the hasty adoption of erroneous conclusions."

It is the most anxious wish of your *corps* of meteorological observers to conduct their investigations "upon sound principles"; and it is in vain that I look for proof that these investigations are not conducted upon such principles, or for any suggestions of *sounder* principles than those which have been adopted. Hitherto we have arrived at no "conclusions", and it is our intention to adopt no conclusions but those based upon a strict and legitimate induction from *facts*.

It is not to be expected that any scheme of meteorological and medical record should at once rise into perfection: time and great care are required to complete the arrangements. We greatly need the supervision of some one profoundly acquainted with meteorological science. This finishing stroke we hope to accomplish ere long, and we may then safely defy the detection of any discrepancies.

With regard to the principle upon which our record of diseases and deaths, in connection with daily meteorological observations, is conducted, your correspondent appears to be singularly unhappy in his objection to it. Every one in the least acquainted with the subject, and with the *desiderata* in this department of medical science, with whom I have had any conversation or correspondence, agrees with us that this is the *only principle upon which we can procure any data worth possessing*, and that it is the only plan upon which we can obtain any useful inductions whatever.

Any one can perceive at a glance that no conclusion can be deduced from the record of a single case of puerperal convulsions occurring at 11 A.M., but when twenty, or fifty, or a hundred cases shall have been recorded, *some valuable facts may possibly be gleaned from the simultaneous meteorological observations*. Your correspondent objects to recording the time of the seizure of the disease, because meteorological observations are not inserted every hour; but surely it is better that they should be recorded twice, or even once daily, than that only the weekly means should be inserted. It is a very strange kind of logic which would prefer *weekly* rather than *daily*, or *twice daily* observations, because it is impracticable to make *hourly* observations. If the weekly means could be a "close approximation to the truth", it is fair to infer that daily, or twice daily, observations will be a still *closer* approximation.

If your correspondent were practically acquainted with meteorology, he would know that barometric and thermometric changes are not ordinarily so sudden and abrupt, but that observations twice daily will give ample guidance for correct conclusions, and very "close approximations to the truth".

The paragraph rather slightly referred to was based upon very extended observations, and was only inserted as a specimen of the kind of research required. It was specifically mentioned that these conclusions, based upon Dr. Moffat's researches, would require to be reexamined; and we are now doing that which will either confirm or disprove, not only these, but many other problems which can only be solved by extensive observations. These were merely given as specimens of what may be accomplished by our scheme, not as final conclusions.

The table, which your correspondent has "tried in vain to understand", I shall be most happy to explain, if he will only let us know what is incomprehensible to him.

It is very evident that Dr. Burder enters but very slightly into the spirit of our scheme when he terms it "ill digested". It had engaged the attention of many minds for a long time; it cost much time, thought, and labour. Of course it could not be perfected at once. It was merely a beginning; but the promoters of it have been amply rewarded by the hearty reception with which it has met. Very many are sanguine of good results from it; and some of your correspondents have expressed themselves in the highest terms: especially would I refer to Mr. Richardson's letter, published some weeks ago. Many gentlemen have privately offered to cooperate with us; and as more space cannot now be devoted to the publication of observations in the JOURNAL, they are now engaged in keeping private records on our plan.

If your correspondent, instead of urging frivolous objections, will *really suggest anything of value*, and will aid us by his private observations and records, he will serve the cause of science much better. The suggestion of "weekly totals" is no improvement whatever upon the old plan, which has been adopted

so long, which has led to such few results, and which it is high time that we improved in some way or other.

In conclusion, will your correspondent be inclined to assist us with his own meteorological and medical observations, if he is in the habit of recording any; and if so, as a preliminary step, will he have the kindness to inform us what instruments he uses, and if they have been compared with any standard instruments?

I am, etc.,

T. HERBERT BARKER, M.D.

Bedford, Nov. 7th, 1853.

THE WEEKLY METEOROLOGICAL TABLE.

LETTER FROM C. L. PRINCE, Esq., TO THE EDITOR.

SIR,—In consequence of Dr. Burder's remarks upon my barometric observations at p. 976 of the ASSOCIATION JOURNAL, I consider it necessary to state, that my barometer has *not* been compared with a standard, but that I purpose having it sent to London, at an early period, to have its accuracy determined. All my self-registering thermometers have been examined by Mr. Glaisher, and were made by H. Barrow, of Oxendon Street.

I am, etc.,

C. LEESON PRINCE.

Uckfield, Nov. 14th, 1853.

CHLOROFORM IN MIDWIFERY.

LETTER FROM EDWARD W. MURPHY, M.D., TO THE EDITOR.

SIR,—Mr. Bloxam's letter has really surprised me as emanating from a gentleman who claims credit for accuracy of reasoning. The two cases of supposed death from chloroform to which I have referred, Mr. Bloxam insists, were caused by chloroform. 1st, Because no other adequate cause was found to explain them; 2nd, Because the symptoms were those well known to be produced by chloroform.

With regard to the first proposition, it is totally illogical. We do not know all the causes of sudden death after labour sufficiently to authorise such a conclusion; and in one of these cases, no *post mortem* examination was made; all the causes were not looked for. Might air, for instance, have entered through the uterine veins and caused asphyxia? With respect to the second proposition, it is untrue; the symptoms, certainly, were those of asphyxia, but not the asphyxia of chloroform. Mr. Bloxam could not produce a parallel case to either of these amongst all the deaths from chloroform. It was the fact that the symptoms differed so strongly from those caused in the fatal cases of anaesthesia, that convinced me and others that chloroform had nothing whatever to do in causing death in either of these cases.

When Mr. Bloxam has had personal experience of the action of chloroform, and time to study accurately its effects, he will, I am sure, perceive more completely the inconclusiveness of this proposition; and until then, he will pardon me if I protest against the conclusion he has now deduced respecting these cases.

I am, etc., EDWARD W. MURPHY.

12, Henrietta Street, Cavendish Square, Nov. 14th, 1853.

NEWS AND TOPICS OF THE DAY.

COMPULSORY VACCINATION ACT.

Colchester Union, Nov. 9th. At a meeting of the Guardians of this Union, summoned specially to consider the above matter, It was resolved—"That the existing Vaccination Contracts be annulled; and that fresh contracts be entered into with every *duly qualified medical practitioner in the union, who shall notify to the clerk of the union his desire to become a contractor.*"

"The fee for each case of successful vaccination, as first mentioned in the sixth section of the new act, to be 2s., and 2s. 6d. for each case as provided for in the latter part of the same section."

The same plan has been adopted at Sunderland and Broomsgrove; and the Poor Law Boards sanctioned this before it was made public.

VACCINATION A DANISH ADJUNCT TO THE MARRIAGE CEREMONY. In France, a certificate of vaccination is exacted for a multiplicity of things; but the Danish government has devised a still more excellent method for propagating the results of the discovery of Jenner. At the altar, the clergyman presents

the certificate, and, if it be not forthcoming, the bride or bridegroom, or both, as the case may be, must proceed to the vestry to have the operation performed, before the conjugal knot can be legally tied.

MONTHLY JOURNAL OF MEDICAL SCIENCE. This Journal, which has for some time borne on its cover the name of Dr. William Robertson as its editor, is now under the direction of Professor Hughes Bennett, of Edinburgh. Dr. Bennett was the editor of the Journal from 1846 to 1849.

EDINBURGH MEDICAL AND SURGICAL JOURNAL. The arrangements for the New Series of this venerable Journal are now completed: and the first number is to appear on January 1st. Dr. Begbie is to lead off with Gout, and Dr. Matthews Duncan is to support him with Cholera in Pregnancy. Other papers are also announced: and, upon the whole, it may be safely predicted that the old Journal is to be resuscitated in all its pristine power. We learn that there are many who regret that an union was not effected between the Quarterly and the Monthly.

MORTALITY ON BOARD EMIGRANT SHIPS. Advices by the *Canada* state that the packet-ship *Washington* had arrived at New York from Liverpool, with nearly 100 deaths from cholera, and upwards of sixty cases on board at the time of her arrival. The numbers are enormous; but the general mortality on board emigrant ships from Liverpool and other European ports to New York is very large. We give the particulars as under from the *New York Herald*.

Although the captains in their reports, with one exception, merely mentioned the fact of such a number having died, it is pretty certain that the disease which carried them off was cholera. Several, no doubt, died by the common diseases, but that cholera was raging on board many of the above-named vessels is beyond all question, from the fact that thirty-three persons who were landed in quarantine were suffering from that epidemic.

DREADFUL SUICIDE. The *Cork Examiner* announces the death by suicide of Dr. Bull, of that city. The unfortunate gentleman had been labouring under an aberration of intellect for some time past; and, though a watch was kept over him, he managed on Thursday evening to elude the vigilance of those employed for that purpose, and hanged himself to a tree in his own garden with the military sash belonging to his son-in-law, Adjutant Dagg. The body was discovered in about an hour after the commission of the fatal deed, and, though some medical gentlemen were quickly in attendance, their efforts were of course quite unavailing. Dr. Bull was distinguished for his humanity and for his skill.

SANITARY PROCEEDING UNDER THE FACTORY ACT. Mr. R. Baker, sub-inspector of factories in the West Riding of Yorkshire, preferred informations before the magistrates at the petty sessions at Otley, near Leeds, on Friday, against Messrs. Baldwin, Brown, and Co., of Yeaton, for not having whitewashed air two mills within the time prescribed by law. It appeared at in the middle of September Mr. Baker had visited these mills and found the whitewashing omitted, and that he then

directed it to be done; but on a subsequent visit paid to the same premises a month afterwards, he discovered that though the walls had been whitewashed the ceiling had not. The magistrates decided it was a bad case, and inflicted two full penalties of £20 and costs.

ROYAL COLLEGE OF SURGEONS:—PASS LIST. The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the college at the meeting of the Court of Examiners, on the 4th instant:—Messrs. John Caldwell, Kew Green; John Richard Davern, Royal Hospital, Chelsea; James Allan Currie, Hon. East India Company's Service, Bengal; John Hodgson Waterhouse, Sheffield; James Askwith Ellis, Nant-y-Glo, Monmouthshire; John Ignatius Purcell Williams, Denbigh, North Wales; and Charles Thomas Wickham, Winchester. At the same meeting of the Court, Mr. William Thomas Wilson passed his examination for naval surgeon; this gentleman had previously been admitted a member of the college, his diploma bearing date July 4th, 1845.

FELLOWS admitted after examination at a meeting of the Council, on the 10th instant:—Peter Yeames Gowlland, Finsbury Square, diploma of membership dated January 28th, 1848; William Martyn, Brompton Row, May 6th, 1839; Henry Thompson, Wimpole Street, Cavendish Square, October 4th, 1850.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH:—PASS LIST, issued Nov. 11th, 1853. **SCOTLAND:**—Andrew Mercer Adam, Glasgow; Peter Divorty, Kintore; William Farquhar, Aberdeen; John Grant, Inverness; Andrew Gray, Gallatown; Alexander Guthrie, Forfarshire; David Hood, Forfarshire; Thomas Dick Laurie, Musselburgh; James W. Norris Mackay, Morayshire; James McDonald, Laurencekirk; Thomas Miller, Coupar-Angus; James Mitchell, Edinburgh; Hugh Noble, Edinburgh; Alexander Mercer Renwick, Musselburgh; James Ross, Fetteresso; Walter Scott, Inverness; Thomas Skinner, Edinburgh; William Stockwell, Musselburgh; Robert Tait, Coldstream; Thomas Crichton Taylor, Dumfries; Robert Watson, Montrose.

ENGLAND:—Stephen Hughes Games, Liverpool; Henry Thomas Sylvester, Devizes; Henry Richard Veale, Cornwall.

IRELAND:—David Campbell, Armagh; Edward Croker, Youghall; James Nicholas Dick, Omagh; William McDonald Kelly, Rosecommon; Hamilton Mitchell, Derry; Edward Clements Nicholls, Dublin.

ABROAD:—Robert Graves Burton, Canada; John Robert Cole, Canada; James Cecil Phillippo, Jamaica; Salvator Aloysius Pisani, Malta; Thomas Rudd, Ceylon; George Scott, Dieppe; James Petrie Street, New Brunswick; George Henry Syme, Cape Town.

MEDICAL SOCIETY OF LONDON. The following papers are announced.

Saturday, November 19th. On the Fibrinous Constituent of the Blood in Relation to Disease. Part III: Clinical. By B. W. Richardson, Esq.

Saturday, November 26th. On Internal Metritis and Uterine Catarrh. By E. J. Tilt, M.D.

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

ATTWOOD, John, Esq., Surgeon, late of Southampton, on board the *Albemarle*, on her passage to Sydney, New South Wales, on April 7th.

HILTON, John, Esq., F.R.S., Surgeon to Guy's Hospital, appointed Consulting Surgeon to the St. Pancras Royal General Dispensary, in the room of the late Bransby Cooper, Esq.

LUDLOW, S., Esq., formerly of the Bengal Medical Establishment, at Bath, on October 17.

MORISON, T., Esq., of the Montrose Lunatic Asylum, elected Medical Superintendent of the Nottingham County Asylum.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.]

*AINSWORTH, James, Esq., Consulting Surgeon to the Manchester Royal Infirmary, at Lower Broughton, Manchester, aged 70, on October 28.

LAMBERT, W. J., M.D., of Thirsk, Yorkshire, aged 36, at Brightstone, Isle of Wight, on November 8.

MEDICO-METEOROLOGICAL OBSERVATIONS

Taken for the Association Medical Journal.

No. VII.—WEEK ENDING 12TH NOVEMBER 1853.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XLVII.

LONDON: FRIDAY EVENING, NOVEMBER 25, 1853.

NEW SERIES.

ADVERTISING! A PEEP BEHIND THE SCENES!!

THE praises lavished by the press upon a certain pease-meal compound, designated by its vendors Revalenta Arabica, are familiar to newspaper readers. Few, however, may have reflected upon the origin and the price of these praises; and, indeed, till now, the data have not been sufficiently precise for the formation of accurate opinions on these points. We therefore believe that it may interest our readers to read the particulars of an instructive peep behind the scenes, which has been afforded by the *Scottish Reformer's Gazette*, a Glasgow newspaper, distinguished for its uncompromising exposures of quackeries and frauds in every form. In the *Gazette* of Saturday last (19th Nov.), the editor communicates the following history, which is instructive to all who are not so well acquainted as we are with the impure mysteries of puffing and advertising.

Messrs. "Barry, Du Barry, and Co.", the pease-meal gentlemen referred to, forwarded to the editor of the *Scottish Reformer's Gazette* an advertisement, of nearly a column in length, announcing "50,000 cures without medicine, inconvenience, or exposure." They required the insertion of this advertisement upon terms and under stipulations stated in the subjoined letter.

"77, Regent Street, London, 7th Nov. 1853.

"To the Editor of the *Scottish Reformer's Gazette*, Glasgow.

"DEAR SIR,—For the sum of £10, we engage 26 insertions of the inclosed advertisement in your paper, in all editions, to appear regularly once every Saturday, commencing on the 12th instant, or this order is cancelled.

"The above price is to include a copy of the paper, with each insertion, regularly forwarded to us; and one of the 26 paragraphs, Nos. 1 to 26, here inclosed, is to appear simultaneously with each advertisement, till all the paragraphs have appeared, when the series is to be recommenced at No. 1.

"This order to be taken by you conditionally, that you comply with all the above terms; and that no attack upon, or allusion to, ourselves or our goods appear in any other shape in your paper than what we have ordered.

"We enclose a cheque for £5 on account, which please acknowledge.

Faithfully,

"BARRY, DU BARRY, AND CO."

The editor acknowledges the "enclosed cheque", by printing it along with the above letter. It runs thus:—

"Messrs. Alexander Duncan and Co., Glasgow, will please credit the *Scottish Reformer's Gazette*, five pounds on our account.—London, 10th Nov. 1853.

"£5.

"BARRY, DU BARRY, AND CO."

The uniform and fearless honesty of our cotemporary with regard to quackeries might, one might have supposed, have protected him from the offer of a bribe: but we are inclined to think that he only received a circular widely issued to the provincial newspapers, the venality of which is so well understood by deceiving advertisers, as to cause

them to issue their bribes indiscriminately, and as a mere matter of trade routine. We lean to this view of the case, from several offers of a somewhat similar description having been made to ourselves. For example, an advertisement was lately sent for insertion in the *ASSOCIATION JOURNAL*, upon condition that the editor inserted the following *morceau* "in his Notices to Correspondents".

"C. J. The appliance of Mr. — is most useful, and has advantages possessed by no other."

Then, again, a firm of beer merchants, brought us editorial puffs from *medical journals*, of their system of doing business (which system, by the way, has led to an offer of five shillings in the pound) with a demand of similar compliments from us, as the *ASSOCIATION JOURNAL* had been equally favoured with their advertisements. The following is one of the puffs to which we refer.

"BAD BEER OR BAD MEASURE. In the number of this Journal for the 8th of January, in an article entitled "Bad Beer or Bad Measure", we drew the attention of our readers to the size of our beer bottles, and pointed out, that the purchaser of every pint bottle of beer was mulcted in at least one-third of his due, solely to enrich the already too-wealthy brewer, or the well, if not over-paid, retailer. As a remedy for this, we observed, that one of two things must happen. Either the size of the beer bottles must be altered, so as to hold the imperial pint or quart; or, if they are to be allowed to remain as they are, they must pass under some other denomination than is at present used to designate them. We are glad to find, that at least one beer firm, Messrs. Earle, Brothers, and Co., of Duncannon Street, Trafalgar Square, have, in consequence, adopted the plan of selling ale and porter in bottles manufactured expressly for them—made to contain the full imperial measure, so that from at least one house in London the public receive their due."—*Medical Times*, April 10th, 1853.

By declining to sell editorial opinions, we assume no personal superiority over our cotemporaries; but we feel that it is an unspeakable satisfaction to ourselves to be under no commercial thralldom, and amenable only to professional opinion.

Authors and publishers do occasionally, though not very often, cast pecuniary snares for favourable notices. One gentleman wrote thus:—"If you review my work favourably, I intend to advertise it extensively in the *ASSOCIATION JOURNAL*." As belonging to the same class, we may mention the case of a firm of publishers who sent us a printed letter (with their advertisement), calling upon us to quote particular passages of a biography which they had recently published. The circular, which now lies before us, is thus expressed:—

"October, 1853.

"Messrs. — present their compliments to the editor, and will feel much obliged by the insertion in his columns of any of the accompanying extracts from —."

Many newspapers have reviewed the book in question, with a selection from the publishers' catalogue of quotations, adopting the racy headings. This is reviewing made

easy: but we must decline all such equivocal assistance. We hold no venal pen; and as the representatives of a professional society, and not of a commercial company, we reject all offers to buy our praises, and resist every attempt to warp our judgment by helps to reviewing.

Advertising and puffing scandals are unfortunately not confined to tradesmen, and second-rate authors. It grieves us to say that in our day the system of pamphlets and circulars adopted by Coldbatch and other noted London empirics of the last century, has been revived with even more than its pristine effrontery. Members of our profession, of various sorts and conditions (excusing themselves by the paltry plea of fear of injury from the jibes and slanders of unscrupulous writers), have stooped to write and revise their autobiographies and biographies; and in some cases, regarding which we have information, to circulate by hundreds a self-concocted history of self, illustrated by a portrait of self, paid for by self. It would be shallow hypocrisy in us to denounce the minor transgressions of commercial men, and make no allusion to the autobiography system which is now degrading our profession, and so widely corrupting the tone of medical society. It is, we hesitate not to say, unprofessional advertising in its most sickening, most demoralising, and most flagrant form. We have no wish to hurt the feelings of any one; but, at the same time, from the strong representations which have been made to us on this subject, we cannot any longer keep silence; and we are all the more inclined to call attention to autobiographical advertising, as the confessions of culprits and other circumstances have given us some commanding peeps behind the scenes.

CLUBBISM OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE unwholesome clubbism of the Royal Medical and Chirurgical Society was prominently noticed by us upon the occasion of the exclusion of Dr. Murphy from the Council, notoriously upon the ground of his not belonging to the College of Physicians of London. We remarked on the 4th of March (p. 181):—

“It is very clear that matters cannot long continue as at present. The tension of feeling is so great as to require relief; and either a reform or a revolution must soon solve the difficulty. Till the voice of the Fellows be heard in the elections, and in pressing questions of internal discipline, distrust must continue to endanger harmony; and what might under more generous auspices become the freest field in the world for scientific emulation among the professors of legitimate medicine, must continue to be a circumscribed club, labouring under the heavy scandal of permitting the homœopathy of Dr. Henriques and Dr. Gully to remain uncensured, while the want of a London title has been found sufficient to deprive Dr. Murphy of that preferment to which he is so richly entitled by his seniority on the list of Fellows, by his upright character, and by the excellence of his professional position.”

Since these lines were written, we regret to say that no change for the better has taken place. Homœopathy, and other forms of quackery, are winked at and dallied with, and the “protection party” still reigns stern and supreme, meting out its favours and its censures with unbridled hand. The hope once entertained of the Society becoming a free and fair arena for scientific emulation is as remote as ever: the outer gate, and the entrance to the inner council,

are both in the hands of a watch by whom merit is not recognised as the password. That this is not an overdrawn statement, is proved from the following narrative of the facts regarding Dr. Ransom's rejection. We have derived our information from sources which we believe to be both trustworthy and well informed; but from the secret nature of the conspiracy, it is quite possible that in some minor details our account may require correction or supplement. However, as regards the leading features of the case, we can vouch for their accuracy. If it can be shown that an honourable man has not been sacrificed to a dastardly intrigue, we shall be the first to correct our statements, and offer penitence to the accused.

Dr. Ransom, of Nottingham, a doctor of medicine of the University of London, came forward, at the late ballot, as a candidate for the Fellowship of the Royal Medical and Chirurgical Society, recommended by some of its most distinguished Fellows, viz., Professors Sharpey, Quain, Walshe, and Jenner, of University College, and Dr. Sibson. At a meeting of the Council, the question of Dr. Ransom's eligibility was raised, upon the ground that he was an illegal practitioner! After some discussion, it was agreed that he should be asked whether he had any other qualification than the M.D. of London University. Dr. Ransom replied that he had none other. At the next meeting of Council, it was proposed by one gentleman that he should be excluded from the ballot as an illegal practitioner. A warm discussion ensued, in which the prevailing sentiment was that Dr. Ransom's qualification was as good as that of any fellow of the Society; and accordingly it was resolved without a division that his name should be inserted in the balloting paper. Notwithstanding this, a party was secretly organised for the purpose of having him blackballed. So cautiously was the plot organised, that none of Dr. Ransom's friends had the remotest suspicion of what was impending; and Dr. Ransom was rejected. It has since transpired that the adverse votes were diligently and secretly canvassed for by certain managing Fellows of the College of Physicians.

The College of Physicians, as a body, are, we trust, clean from this dirty trick of clubbism. Be that as it may, the circumstances connected with the rejection of Dr. Ransom require to be well investigated. As the case now floats upon the surface of society, it cannot but exasperate the provincial physicians against the proposed charter of the College of Physicians, which extends the jurisdiction of the College from a metropolitan circuit of seven miles to the whole of England. It behoveth provincial physicians to consider well their present position and their prospects under the contemplated charter. The fact upon which they are called on to ponder is this:—A physician, and a very talented and respected member of the profession, has been blackballed at the Royal Medical and Chirurgical Society because he was practising at Nottingham without the license of the College of Physicians of London. Had Dr. Ransom been practising in London there might have been a slight ground for the proceeding, but as the College only holds legal jurisdiction within seven miles of the metropolis, we cannot see even a pretext for inflicting upon him so gross an insult, and through him, slighting the majority of the provincial physicians of England—for the majority of that body are not connected with the institution in Pall Mall.

Again, a scientific society, embracing so large a number

of Fellows of the College of Surgeons, and of general practitioners, ought not to be made the arena for the battles of contending corporations: and a great effort ought to be made to purify its ethics and to emancipate it from the dominion of those who have so degraded and so disgraced it. We trust that Dr. Ransom may again be put up to the ballot; for we have no doubt that the profession would then be shown how guiltless were the majority of the fellows of attempting to fix an unmerited stigma upon a physician who is of unimpeachable reputation as a man of good morals, gentlemanly character, and scientific distinction.

Two evils, then, are rendered painfully conspicuous by Dr. Ransom's rejection:

FIRST:—the intolerance of the managing party in the College of Physicians: and

SECOND:—the existence of the Royal Medical and Chirurgical Society as a clique-ridden club, and not as an arena open to all honourable cultivators of medical science.

MEDICAL STUDENTS.

We feel assured that the proposal made by Dr. GOLDING BIRD, in his letter at p. 1043, for the benefit of medical students, will meet with cordial support in many a home visited by this JOURNAL. In addition to the measures suggested by Dr. Bird, we would urgently direct the attention of the teachers in the different medical schools to the great advantages which would arise from the suppression of late lectures. Medical lectures after dark throw young men unnecessarily upon the streets, destroy all possibility of cultivating studious habits, and notoriously cause many a volatile youth to finish the evening in billiard-rooms or casinos. Upon a future occasion we propose to return to this subject; but in the mean time we very earnestly ask associates, resident in the seats of medical learning, to consider what can be done in the direction pointed out by Dr. Golding Bird.

ASSOCIATION INTELLIGENCE.

PAYMENT OF SUBSCRIPTIONS:—NOTICE BY THE SECRETARY.

At a meeting of the Central Council, held on Saturday, November 10th, 1853, Sir CHARLES HASTINGS, M.D., President, in the Chair.

It was resolved unanimously—

“That the Secretary do strictly enforce the 24th Rule, relative to the supply of the JOURNAL to members who are in arrear.”

The Secretary of the Association begs to call the attention of members to the above resolution, and to the 24th Rule, which is as follows:—

“If any member's subscription remain unpaid twelve months after it shall have become due, the MEDICAL JOURNAL and other publications of the Society shall be withheld from such member till his arrears be paid.”

He begs to inform them that for the future this rule will be enforced; and he hereby gives notice that all members who have not paid their subscriptions for the years 1851 and 1852, will not receive the Journal after Friday, December 2nd, till such arrears are paid; and those members who shall not have

paid their subscriptions for the current year before the 1st of January, 1854, will subject themselves to Rule 24.

The Secretary will be obliged to the Honorary Local Secretaries, if they will be pleased to transmit to him forthwith a list of those members who have paid them their subscriptions, so that he may be enabled to avoid the unpleasantness of making application to gentlemen who have paid.

JAMES P. SHEPPARD, *Secretary to the Association.*

TO CORRESPONDENTS.

MILITIA SURGEONS are requested to forward the iraddresses to L. W., at the ASSOCIATION JOURNAL OFFICE, that they may receive invitations to a meeting which it is proposed to hold next month at Birmingham. We are obliged to postpone till next week the letters we have received on this subject.

ADVICE GRATIS. Letters in our next.

VACCINATION ACT. Letters in our next.

NEWS AND TOPICS OF THE DAY.

HARVEIAN SOCIETY. This Society meets at 64, Edgeware Road, on the first and third Thursdays of each month, from November to June—excepting Christmas week. The following is the business announced for the three ensuing meetings:—

Thursday, December 1st. On Certain Morbid Conditions of the System which may become Cachectic. By Thomas Hodgkin, M.D. [This is intended to be a continuation of a former paper by the author.]

Thursday, January 5th. This being the Anniversary Meeting, the Council Report will be read, and the new officers will be elected.

Thursday, January 10th. On the Uses, Dangers, Doses, and Modes of Administering of certain Powerful Medicines. By John Rose Cormack, M.D.

MEDICAL SOCIETY OF LONDON. The following papers are announced.

Saturday, November 26th. On Internal Metritis and Uterine Catarrh. By E. J. Tilt, M.D.

Saturday, December 3rd. On the Pathology and Treatment of Swelled Testicle. By J. L. Milton, Esq.

Saturday, December 10th. Pale Urine considered as a precursor of Disease. By R. Drutt, M.D.

Saturday, December 17th. Source of Hæmorrhage in Partial Separation of the Placenta. By F. W. Mackenzie, M.D.

MEDICAL BENEVOLENT COLLEGE. On Sunday last, the claims of this National Institution were very ably advocated by the Rev. W. Harrison, M.A., who preached a most eloquent and impressive Sermon to a crowded congregation, amongst whom were present H.R.H. the Duchess of Cambridge, and the Princess Mary. The powerful appeal of the reverend gentleman was liberally responded to. We have pleasure in stating that other clergymen have kindly promised to preach in aid of the funds of this Institution. Agreeably with the laws of the College, Mr. Harrison, and Mr. Hamilton, in whose Church the Sermon was preached, will be constituted Honorary Life Governors.

ERRATUM.

In Mr. Ansell's "Facts and Opinions relating to Tuberculosis," No. II, in the ASSOCIATION JOURNAL for October 14th, at page 895, column 1, line 2 from the bottom, for "sixteen years," read "ten years".

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London: or to the office of the Journal. Letters requiring immediate attention and revised proofs ought invariably to be sent to Putney.

[*News and Topics continued at page 1044.*]

ORIGINAL COMMUNICATIONS.

FACTS AND OPINIONS RELATING TO TUBERCULOSIS, WITH COMMENTARIES.

By HENRY ANCELL, Surgeon.

NO. III.

A SERIES of statistics, under the title "*Decennium Pathologicum*", has been published by Dr. T. K. Chambers in the *Medical Times and Gazette*. It consists of the results of all the *post mortem* examinations made in the mortuary of St. George's Hospital during ten years, from December 31, 1840, to December 31, 1850, and is intended, especially, as a contribution towards the pathology of chronic disease. The subject of tuberculosis is complete, although the papers are still continued in the *British and Foreign Quarterly Review*. The philosophical spirit and classical tone which characterise this work give me the assurance that its author is anxious for discussion and inquiry as to the nature and bearing of the facts developed, and the deductions drawn from them; and that, after the very great labour he must have bestowed, it will be gratifying to see the subject of it canvassed, although, on some points, difference of opinion may be elicited.

The circumstance which first strikes the attention, on perusing that portion of the series relating to tuberculosis, is the sense in which Dr. Chambers employs the term. In the first place, it is taken for granted, that the word is understood in the same sense by a "practical majority" of those who use it; and in enumerating the deaths "with" tuberculosis, the presence of tubercle, ascertained *post mortem*, is adopted as the test of its existence. Tuberculosis is also a "morbid action", capable of receiving future elucidation from chemistry and the microscope; and its effects on the viscera and the constitution at large are mentioned, "the lungs being the chief object of its attacks." The cases comprised in the term, as employed by Dr. Chambers, include both the medical and surgical cases in which tubercle was found after death. It thus includes cases of lumbar abscess, diseased bones, and other scrofulous affections; excluding all such as had proved fatal without the deposit of tubercle. According to this definition, a scrofulous disease of a joint is a case of tuberculosis, provided a few tubercles have been deposited in the lungs or any other structure; but a similar case, occurring, for instance, in the offspring of consumptive parents, with well marked predisposing signs of a tuberculous habit, and all the symptoms of constitutional disease, is not a case of tuberculosis, if tubercles do not exist after death.

The "Tuberculosis" of Müller, Rokitansky, and others, is the "Tuberculous cachexia" of Sir James Clark. The latter describes it as "a morbid condition of the system, which precedes and attends tuberculous disease." Lebert employs the word in the same sense, and remarks that "in general tuberculosis, a true ulcerous diathesis, though not one depending immediately on tubercle, takes place." Louis very frequently describes tuberculous ulcers, not produced by tubercle, in phthisical subjects.*

Without dwelling on the propriety of the use of the word, in an etymological point of view, I have adopted it in my work, in the sense in which I found it employed by these practical writers, only that I have treated of it strictly as a morbid condition of the blood; and, having advanced what I believe to be irrefragable proof, that scrofulous affections and tuberculous affections own the same parentage, I include within its meaning the diseased condition which precedes and accompanies scrofulous ulcerations, and all scrofulous local affections. It will thus be seen that "tuberculosis" comprises all those diseases grouped together by the Registrar General (as I think, very properly,) under the designation of "tubercular diseases", without reference to the actual existence of tubercle. We well know, that a vast majority of scrofulous subjects develop tubercle before death, although, in a minority, this morbid

deposit is absent; the disease being essentially the same in both cases. According to the test of the existence of tuberculosis, furnished by pathological anatomy, and adopted in the "*Decennium*", an individual who dies from the effects of amputating a scrofulous limb, if no tubercle were found *post mortem*, would not be regarded as affected with tuberculosis; although, by deferring the amputation for a very short period, tubercles would assuredly develop themselves. Although tubercle is the true constitutional element of tuberculosis, it is not, and cannot be regarded, as the only test of the existence of the disease.

Dr. Chambers is himself unable to adhere, in all cases, to this practical test of tuberculosis; since, when we arrive at his enumeration of the tuberculous affections of the kidneys, we find fifteen cases of "scrofulous degeneration." Three occurred in subjects without tubercles in the lungs. The remark occurs, that "these large masses, constituting the form of disease called 'scrofulous degeneration', have such a different appearance from the small, hard, shot-like tubercle, that were they not the consequence of the same diathesis" (the italics are my own), "one could hardly believe in the relation between them."

Again, the eighth paper contains an enumeration of "*Brain Diseases without Cerebral Tubercle in Tuberculous Persons*"; and we are informed, very truly, that besides those cases where actual deposit is developed in the head, there are many instances of morbid cerebral action occurring in patients affected with tuberculosis, some of which "appear really connected with the diathesis itself." It is shewn statistically, that idiopathic inflammation, of the membranes at least, is almost peculiar to the tubercular diathesis. But, again, the test of the existence of the diathesis is the existence of tubercle in some other organ, although not in the brain. Can it be doubted that idiopathic inflammation of the brain, thus shewn to be peculiar to the tubercular diathesis, may, and frequently does occur, without the deposit of tubercle in any other organ? Treating of a disease which forms so large a portion of the experience of every practitioner, I generally avoid any appeal to my own; but on this point I may state, that having from the commencement of my practice taken an especial interest in the cerebral affections of infants, and examined every case *post mortem*, when allowed to do so, it has occurred to me, again and again, to meet with the pathological results of inflammation of the brain and its membranes as the cause of death, without a single tubercle in any organ. I have known two and three children of the same tuberculous family die of cerebral affections, in some of whom tubercles existed in the brain or elsewhere, while, in others, not a trace of the deposit could be detected in any structure; and I am satisfied that the experience of others must be similar.

In the instance first given, it is virtually admitted that "scrofulous degeneration" of the kidney depends upon the same diathesis, the same "morbid action", as tubercle; and the question arises, why should not scrofulous degeneration of the knee, ankle, or elbow-joint, and of other glands and viscera, be so regarded? In the second instance, it is admitted that idiopathic meningitis is almost peculiar to the tubercular diathesis; and yet, according to the distinction drawn by those who understand the word tuberculosis, in the practical sense as tubercle, the occurrence of a few tubercles in the spleen, or some other organ, which can only be known after the death of the patient, determines whether it is or is not to be regarded as a case of this disease.

I make these remarks with no view to diminish the importance of Dr. Chambers's labours, the results of which I regard as of the utmost value, but simply for the sake of a right understanding of the subject. In the use we make of the statistical facts relating to tuberculosis contained in these papers, we have then to bear in mind that these are not the statistics of phthisis alone, nor of scrofula alone, nor of scrofula and phthisis together: they comprise the deaths from phthisis in its various forms—pulmonary, intestinal, peritoneal, etc.; and from scrofula where tubercle has been deposited; excluding all cases of scrofula, and of

every form or grade of tuberculous disease, in which it is not deposited. They are, in fact, *par excellence*, the statistics of *tubercle*, and include every case in which this morbid deposit was found, whether the death of the patient had been produced by *scrofula*, or consumption, or by any other disease.

In St. George's Hospital, during the ten years over which this series of statistics extends, the number of autopsies was 2,161: males, 1,425; females, 732; and four cases in which the sex was not definitely recorded. Tubercle occurred in 566* of the above number of cases; 396 were males, 167 females, and 3 sex unknown. In the cases with tubercle, the deposit was found—

	Cases.	Males.	Females.
In the lungs alone, in	214	148	65
In the lungs, conjointly with other organs,	303	210	91
In organs and structures exclusive of the lungs,	49	33	11

Of the 517 cases in which, as above shown, tubercle occurred in the lungs—in 117, the deposit was in a solid state, without having undergone any process of softening; 119 being males, 51 females, and 1 sex unknown: in 340, the tubercular matter was softened into vomice; 236 being males, and 102 females: in 3, calcareous matter was found in the lungs, with tubercle in some other part of the body.

From the numbers given, it is deduced that tubercle was met with in 26.1 per cent. of the total number of autopsies. Dr. Chambers attaches much importance to these proportions, and considers that on our dependence upon them hang answers to scientific and social questions of a momentous kind. He regards them as a fair representation of the proportionate number of cases of tubercle occurring in those classes of the population at large from which hospital patients are derived, believing that there is no source of fallacy from which we can infer that the percentage is higher, although there are several circumstances which may render it lower. Of the latter, the chief are—1. By a rule of the institution, patients suffering from consumption are not admissible; 2. The Consumption Hospital at Brompton withdraws a portion of the subjects of consumption from other metropolitan institutions; 3. The number of persons, otherwise healthy, brought into hospitals for severe accidents, tends to augment the mortality with sound viscera above that of the country at large. From these premises, Dr. Chambers infers that the percentage of cases of tubercle in St. George's Hospital may be taken as representing the minimum for the population out of the hospital, which minimum is accordingly about 1 in 3.8 of the total number of deaths.

On taking into account the causes above enumerated as tending to diminish the percentage within the hospital, which causes must operate to a very great extent, the actual percentage for the population at large, according to this test, must be very considerably raised. It would reach, probably, one-third or one-half of the total number of deaths.

The author, as before stated, does not appear to admit the possibility that the proportion of cases of tubercle in St. George's Hospital can be higher than in the same classes of the population at large; and yet, as it appears to me, his own statistics render such a conclusion by no means improbable.

According to the returns furnished to the Registrar-General, the deaths from tuberculous diseases, in the general population, bear the proportion of about 1 in 6.3. In many of the cases that contribute to the sum total of these diseases, tubercle, as we have before pointed out, is absent; and all such cases are excluded from the statistics of tubercle in the *Decennium Pathologicum*. On the other hand, there are many cases in the tables of the Registrar-General, under other nosological designations, as, for instance, diabetes and albuminuria, in which tubercle would occur as a complica-

tion, although tuberculosis was not returned as the cause of death. These latter cases are all included in the statistics of tubercle before us. Looking closely through the nosological list of the Registrar-General, and calculating the number of cases of tubercle which might be added to his sum total of tuberculous diseases, from the proportion in which tubercle has been found as a complication in such diseases, and setting these omissions against the cases in the registry registered as tuberculous diseases, but in which tubercle could not be found, uncertain as such a calculation must be, I still think that, after the earliest period of life, the ratio in the Registrar-General's tables is rather above than below the truth; that is to say, in the general population, the proportion of cases in which tubercle occurs does not exceed 1 in 6.

But there is a circumstance of much more weight, upon which Dr. Chambers relies in support of his position, viz., that the classes from which hospital patients are derived are more liable to tubercle than other classes of the community. I have stated some very important facts (*On Tuberculosis*, p. 455) from M. D'Espine, of Geneva, and other writers, illustrating the comparative frequency of *scrofula* and phthisis in the rich and poor, from which it appears that, in the countries referred to, these diseases are twice as frequent in the latter as in the former. From these facts, I have no doubt that the ratio of deaths "with" tubercle, for those classes from which hospital patients are derived, is higher, in the main, than the ratio above given from the tables of the Registrar-General. This circumstance is in favour of Dr. Chambers's inference. At the same time, I do not believe it sufficient to account for the whole difference. No doubt hospital patients are derived from the various orders of poor; but are they derived from those most liable to tubercle? As respects the *Decennium Pathologicum*, the rules of St. George's Hospital have already, in part, afforded an answer to this question. Independently of this, in the metropolis generally, hospital patients consist of the recipients of severe accidents; they contain also a very large proportion suffering from various diseases produced by the abuse of alcoholic fluids, who are by no means the most liable to death either from tuberculosis or with tubercle. (*On Tuberculosis*, p. 456.) It is to be doubted whether, of the different orders of poor, the poorest and most degraded are more liable to tubercle than some of those in better condition, rarely becoming the subjects of hospital relief, but leading sedentary lives in unwholesome occupations. (*Idem*, p. 464.) Considerations such as these lead me to doubt the propriety of accepting the proportion of cases in which tubercle was found in the mortuary of St. George's Hospital, as a standard for the population generally, even among the classes from which hospital patients are derived.

On looking more closely into the particulars of the occurrence of tubercle in the patients of St. George's Hospital, it appears that, in 171 of the cases contributing to the total number (566), the morbid deposit was met with in the lungs, in a solid state, "without having undergone any process of softening". The subjects of tubercle in this state died, for the most part, either from accidents, or from other diseases differing totally from tuberculosis. There can be no question that the greater number of such cases, whether occurring within or without the walls of a hospital, would be excluded from the Registrar-General's return of tuberculous diseases. Deducting these cases of tubercle in the earliest stage, the number remaining is 395, which diminishes the proportion from 1 in 3.7 of the total number of deaths to 1 in 5.4. Although the circumstances do not, perhaps, justify us in deducting the whole, it is quite clear that the proportion of cases of tubercle in St. George's Hospital, as compared with the proportion of cases of tubercular diseases returned to the Registrar-General, is very materially augmented by this class of cases.

We are thus brought to the question, whether, in the classes of the population which correspond with the inmates of St. George's Hospital, for every five cases of recognised tubercular disease, there are two cases at least returned under

* The numbers in this paper are extracted from a copy of the original papers by Dr. Chambers, corrected by the author, with the use of which he has been kind enough to furnish me, and which he purposes to deposit in the Library of the Medico-Chirurgical Society.

other denominations, in which, if pathological statistics could be obtained, it would be found that tubercles exist. I have already admitted that a certain proportion of such cases must be allowed for; but, falling back on my own observation, with all I can collect as to the frequency of tuberculosis in combination with other fatal diseases, availing myself, also, of the statistics contained in the *Decennium Pathologicum*, I do not think anything like so large a number occurs out of hospital practice.

This point can be determined, statistically, only by a very extensive range of observations both within and without the walls of our hospitals; and, although it should be shown that tubercle occurs as frequently in all our general hospitals as at St. George's, we are not justified in the assumption that it is equally frequent in the same classes of the population out of the hospitals. The grave question here presents itself, whether tuberculosis is not produced under the circumstances associated with a residence in hospitals? The question is not entirely new, although it appears to have met with very little attention. I have alluded to it in my work, and have given some facts from MM. Rilliet and Barthez, tending, as far as children are concerned, to answer it in the affirmative. I have since met with the statement, that, of 4,000 children admitted into the Foundling Hospital at Paris, 3,000, or 75 per cent., die; of which a very large proportion, say two-thirds, are carried off by tuberculosis. In the first of this series of papers is shown the excess of tuberculosis in the army, and that the more immediate observers refer it, in part, to defective barrack accommodation. The inmates of prisons, in all countries, appear to be more liable to the disease than their respective populations. In addition to the reasons assigned by Mr. Simon for the belief that newly formed or "young blood" is most easily rendered tuberculous, I have advanced others to show that, where a large proportion of newly formed blood is circulating in the vessels, even in adults, as after hæmorrhages, fevers, and other causes of deterioration and waste, it is extremely liable to take on the tuberculous transformation, especially under unfavourable circumstances of hygiene. A very few weeks is sufficient to produce tuberculosis in healthy animals under such circumstances: and it may establish itself in the sickly or convalescent even more rapidly.

I am the more surprised that Dr. Chambers has not admitted that the frequency of tubercle in St. George's Hospital may in part be the result of hospital residence and regimen; since, in remarking upon its frequency in the foreign hospitals for children, he states that it is doubtful how far the circumstance may not originate in the unfavourable conditions under which the patients are placed, stating, very justly, that, if it own this origin, such institutions are not the criterion by which to judge of the liability of children at large. Dr. Chambers considers that these unfavourable conditions arise from the vast and incautious scale on which the public care of young children is undertaken on the continent, alluding, I presume, to overcrowding. Our general hospitals may not be so chargeable with the error of overcrowding, although the congregation of twenty or twenty-five sick persons constantly in one room is no unimportant affair; but it must be remembered, that overcrowding is not the only circumstance connected with hospital residence which calls for consideration.

I have designated this as a very grave question, and as such I regard it. It bears upon the propriety of establishing hospitals for infants and young children, also of long continued residence in hospitals, for the treatment of chronic diseases, even in adults, and the period they ought to remain in hospital after acute diseases; it is also one of the most important considerations in reference to the proper management of patients, in all cases, during protracted convalescence.

Of the 566 cases of tubercle, it was found in 27.7 per cent. of the male, and 22.8 per cent. of the female subjects—a difference, the author thinks, entitling us to a decided opinion of a real excess of liability in the male sex, "in the world in general"; and this tendency Dr. Chambers regards

as dependent on the nature of the morbid process, and on the essential differences of the sexes. During the same decennium, the number of cases of tuberculosis pulmonalis (phthisis), in London alone, returned by the profession to the Registrar-General, was 68,315; and, for the whole of England and Wales, it could not be less, in round figures, than 500,000. These figures exclude a very large proportion of cases of scrofula, tabes mesenterica and hydrocephalus, and may therefore be received as very much within the real number of cases in which tubercle occurred in the general population. The ratio per cent. of the number of cases of tubercle met with at St. George's Hospital, to the cases of phthisis alone in London, is thus only .8, or less than a unit. The ratio per cent. to the cases of phthisis, in England and Wales, cannot amount to .1. The difference in the liability of males and females, as indicated by these 566 cases, is 4.9 per cent. By what rule then, is a difference of 4.9 per cent.—of less than 1 per cent. of the total number of cases—to be received as the exponent of a difference in the total number of cases occurring in London; or a difference of 4.9 per cent. of 1 per cent. as a fair criterion of the relative liability of males and females over the whole of England and Wales?

In the medical report of the Consumption Hospital, which extends over six years, a difference of about 23 per cent. was also found in favour of the greater liability of males; but, in making a sum total of all the *in* and *out*-patients of this hospital, affected with phthisis, during the six years over which the report extends, and of all the cases of tubercle observed at St. George's Hospital during the ten years, each reduced to the mean of one year, and comparing them with the number of cases of death from phthisis in London during one year, they amount barely to 11 per cent.; and for England and Wales they cannot amount to 1.5 per cent., showing that even this number of cases (4,924) is totally inadequate to justify a conclusion on this point.

The author does not afford any proof that the patients of St. George's Hospital, who furnish the cases of tubercle, are a fair example of the population generally who become tuberculous, or that there are no circumstances that can operate specially in producing an excess in the male sex in one locality, and the female sex in another. If it were not that Dr. Chambers's view is supported by certain records showing an excess of males in several large cities, against which there are facts which militate in the other direction, we should be thrown upon the doctrine of chances; that is to say, we could only admit the bare possibility of the proportions in the whole mass being as they occurred in the hospital, on the assumption that we know nothing to the contrary.

I have elsewhere entered very fully into the question of the relative liability of the sexes to tuberculosis, and have brought a great variety of statistics to bear upon it. In some localities and populations, and according to some authorities, the liability was found to be in excess in the male sex; in other instances, and on a larger scale, in females. In 1847, the proportion of deaths of each sex to the population of England and Wales (17,124,038), returned to the Registrar-General, was—

	Males.	Females.
From tubercular diseases,	1 in 252.1 ...	1 in 251.7
From phthisis,	1 in 373. ...	1 in 310.

The greater difference in phthisis, as compared with tubercular diseases in the aggregate, arising partly from the greater liability of males to different forms of scrofula. I see no reason, from the statistics of St. George's Hospital, to modify the conclusion I then arrived at; viz., that there is *presumptive evidence of the female sex operating in a slight degree as a predisposing cause of the disease*; but that *sex* can have little influence, since, in some localities, the disease prevails most in the male, in others in the female sex: and sometimes, when the investigation has been made in the same place at different times, the results first arrived at have been subsequently reversed.

In the next place, the author, proceeding upon the assumption that the male sex is most liable to tubercle,

arrives at the conclusion, that in this sex the lungs acquire this liability less than the rest of the body. This general inference is drawn from the fact that, in the autopsies wherein the lungs presented tubercle, there was a much smaller preponderance of the male over the female sex, than where the lungs were excluded. "A woman is less likely than a man to become tuberculous; but, if she does become so, her lungs are more likely to suffer than those of the other sex." This seems to show, the author proceeds, "that the remarkable liability of the pulmonary organs, in both sexes, is not due to any social or physical circumstance to which males are most exposed", but is dependent on the nature of the morbid process, and the essential differences of the sexes; and it excludes climatic influences, variations in temperature, and humidity, to which men are certainly the most exposed, "as causes of tubercle in those organs which of all internal viscera are most laid open to these changes."

I have elsewhere taken great pains to establish the important etiological distinction between the causes of tuberculosis as the constitutional disease, and the causes of local disease in the subjects of this general or constitutional disease. Now, whether we regard the aggregation of tubercle in the lungs, especially, as part and parcel of the constitutional disease, and as a natural, although it cannot be regarded as a necessary effect of its causes, or whether we regard the localisation in a particular organ as an accident produced by some cause superadded to that of the original disease, the inference, that the liability of the pulmonary organs is dependent on the nature of the morbid process, and is not due to any social or physical circumstance to which males are most exposed, does not appear to me to be valid. As respects the constitutional disease, I have referred, for instance, to a great number of well authenticated facts tending to show that deficiency of exercise has an etiological claim at least equal to that of any other reputed cause, taken singly. The frequency of tuberculosis in sedentary females, and among those engaged in sedentary occupations, is a case in point. This is surely both a social and a physical circumstance. If the conclusion applies only to the determination of the aggregation of tubercle in a pre-existing tuberculous habit, then again I say that, even admitting the proportions to be as indicated by this limited number of cases, it by no means follows from the premises, for instance, that an unnaturally quiescent state of the lungs, maintained habitually—a physical, and, considering the habits of large classes of the community, male and female, an eminently social circumstance—is never the cause of the lungs especially becoming affected.

Under this head, however, it is agreeable to find that on one point, which may ultimately assume a most important practical bearing, the particular lines of investigation pursued by Dr. Chambers and myself respectively, have led us to analogous conclusions. Dr. Chambers remarks, that the lungs are made for receiving atmospheric air of all descriptions, referring to its qualities of temperature, humidity, and the like; and he thinks there is more evidence for believing that those varieties and vicissitudes to which males are most exposed are rather beneficial to the organs of respiration than otherwise. He treats the idea of a changeable climate, and exposure thereto, being the causes of tubercle developing itself in the lungs, as a supposition, and condemns the too exclusive care often exercised to keep those who have an hereditary tendency to tuberculosis in an equable air, and to defend them from all extremes of heat, cold, and moisture. Many very remarkable facts confirmatory of this view have been elsewhere quoted. The circumstance is confirmed also by the medical statistics of the army and navy, comprised in the second of this series of papers; and it is no less remarkably so by the fact that, of the reported cures of consumption extant, the greater number have taken place under a system of exercise and free exposure to the vicissitudes of the open air in inclement climates.

In my work on *Tuberculosis*, I have given what I conceive to be some very strong statistical proofs of the ex-

istence of a *law of decrement* as to the susceptibility of the human constitution to tuberculosis. This law appears to manifest itself from the age of fifteen or twenty years onwards; and there are also reasons for entertaining the opinion that it is uniform; that is to say, in operation from birth to old age. (Table xix, page 408, *et passim*.) Should such a law be proved to exist, it is one of the highest importance, both in a theoretical and a practical point of view. I accordingly turned with some anxiety to those parts of the *Decennium Pathologicum* which relate to the influence of age, for the purpose of ascertaining whether, in the main, the facts tend to confirm or to invalidate the law.

From Dr. Chambers's corrected copy, I extract the following table:—

TABLE XVIII.—*The ratio per cent., in which Tubercle was found in the 2,161 autopsies at different periods of life.*

Periods of life.	Males.	Females.	Total.
In 94 males and 60 females, from birth to 15 inclusive	27.6	28.3	27.9
In 377 males and 259 females, from 15 to 30 inclusive	36.6	34.3	35.8
In 472 males and 179 females, from 30 to 45 inclusive	28.1	10.5	25.8
In 299 males and 139 females, from 45 to 60 inclusive	24.0	10.0	19.6
In 109 males and 58 females, above 60	11.0	1.7	7.7
In 74 males and 37 females, of unknown age	18.9	29.7	25.2
In total of 1425 males and 732 females, and 4 of unknown sex, of all ages	27.7	22.8	26.1

On examining this table, we find, whether we take the ratio for males or females, or the total per centage, including both, that there appears to be an uninterrupted decrement from the age of fifteen years onwards. As respects the earlier periods of life, if we look to the very high percentage in the above table, and connect it with the fact that, at St. George's Hospital, infants and very young children are rarely admitted for such diseases as tubercular meningitis, tabes mesenterica, and phthisis, and also with the large proportion of deaths produced by these diseases, even during the first years of life, in the population at large, and associate this again with the greater frequency of curable scrofula in early life, we find a remarkable confirmation of the law in question.

It is true that in subsequent tables, where the 214 cases in which tubercle occurred in the lungs alone, and the 303 cases in which it occurred in the lungs together with other organs, are each separately divided, according to periods of life, the law does not appear to hold good with respect to the first group, in the earliest period; but of this circumstance there is a very simple explanation in facts admitted by all pathologists, the exception thereby proving the rule. When tuberculosis, even understood in the sense adopted by Dr. Chambers, sets in with the deposit of tubercle, the tubercles occur in a plurality of organs in the same individual much more frequently in children than in adults. In 312 tuberculous children examined by Rilliet and Barthez, a single organ was tubercular in 48 cases only; and of these 48 cases, the lungs were not the organs affected in the majority.

In the 566 cases before us, tubercle was found in different parts of the body exclusive of the lungs, forty-nine times, or in 8.6 per cent. In an aggregate of 1,136 cases of tubercle in various organs of the body, at all ages, collected into a table from the works of Louis, Lombard, Boyd, Rilliet and Barthez, and Papavoine, and introduced into my Treatise, there were 106 in which the lungs were exempt. This gives 9.3 per cent. These statistics teach us, that in cases of tuberculosis, viewed as a general disease, we are not to look exclusively to the lungs,

at any period of life, for that organic mischief which, if allowed to establish itself, too certainly entails a rapid and fatal termination.

Of the 49 cases in which the lungs were free from tubercle, the frequency with which the other parts were affected is shewn in the following table:—

TABLE XIX.—*The organs affected in 49 cases where the lungs were exempt out of a total of 566 cases of tubercle; distributed in quinquennial periods of age.*

Seat of tubercle.	A.	B.	C.	D.	E.	F.	G.
Kidneys	1	4	5	4	1	—	15
Bronchial glands	1	5	3	—	—	—	9
Peritoneum	6	3	1	2	—	—	17
Abdominal glands	1	2	1	1	—	—	6
Parts of generation	—	1	—	1	1	2	5

Pericardium	—	1	1	—	—	—	2
Cellular tissue and muscles	—	1	1	—	—	—	2
The shaft of the femur ..	1	—	—	—	—	—	1
Spleen	—	1	—	—	—	—	1
Dura mater	—	1	—	—	—	—	1
Nervus abducens	—	—	1	—	—	—	1
Axillary glands	—	1	—	—	—	—	1
Cervical glands	—	1	—	—	—	—	1

A. In 154 cases of all diseases examined, from 1 to 15.

B. In 636, from 15 to 30.

C. In 650, from 30 to 45.

D. In 498, from 45 to 60.

E. In 167, above 60.

F. In 112, of doubtful age.

G. Total in 2161 cases.

The more prominent particulars relative to those cases in which this morbid deposit was found in the lungs, is shewn in—

TABLE XX.—*The organs affected in 517 cases where tubercle occurred in the lungs; out of a total of 566 cases of tubercle, and 2,161 cases of all diseases examined; distributed in quinquennial periods of age.*

Seat of tubercle.	A.	B.	C.	D.	E.	F.	G.
Intestinal canal	10	71	37	14	—	9	141
Mesenteric glands	17	37	26	9	1	3	93
Kidneys	6	46	26	11	1	1	91
Peritoneum	6	23	8	4	—	1	42

Male organs of generation	—	3	1	—	—	1	5
Female organs of generation	—	—	—	2	—	—	4
Axillary and cervical glands	1	—	2	1	—	—	4
Anterior mediastinum	—	3	—	—	—	—	3
Pancreas	—	—	1	—	—	—	1
Cranial bones	—	—	1	—	—	—	1

A. In 154 cases of all diseases, or in 37 cases of tuberculosis of the lungs, from birth to 15 inclusive.

B. In 636 of all diseases, or in 211 of tuberculosis of the lungs, from 15 to 30 inclusive.

C. In 650 of all diseases, or in 155 of tuberculosis of the lungs, from 30 to 45 inclusive.

D. In 498 of all diseases, or in 77 of tuberculosis of the lungs, from 45 to 60 inclusive.

E. In 167 of all diseases, or in 11 of tuberculosis of the lungs, above 60.

F. In 112 of all diseases, or in 26 of tuberculosis of the lungs, of unknown age.

G. In 2,161 cases of all diseases, or in 517 of tuberculosis of the lungs, at all ages.

For a long period it was made a point of practical bear-

ing, and one of some importance, that tubercles are more frequently formed in the left than in the right lung; and the investigations of the author not supporting this dogma, he is somewhat satirical upon those who repeat it. I am happy to find that I am not included in the censure implied. From an examination of the statistics of various pathologists, I arrived at the conclusion that it had not been proved that either lung is more subject to the deposit than the other. Louis and Andral found it more frequently in the left; Hope in the right. Its relative frequency in the present statistics was as follows:—

	Right Lung.	Left Lung.	Both Lungs.
Crude tubercle	29	21	110
Softened tubercle	58	62	219
	87	83	329

So that, as the author remarks, its localization in either lung appears from this series of cases to be independent of its essential nature, and what may be called accidental.

On the other hand, in Dr. R. P. Cotton's work, recently published, I find the following table, in reference to which it should be remarked, that it is a table of cases observed in the out-door department of a hospital, during life, and refers to the epochs at which the histories of the cases were taken. Its accuracy is wholly dependent upon the perfection of diagnosis in the observer.

TABLE XXI.

The Position of Tubercle in 1000 Cases of Phthisis.

	Right Lung.			Left Lung.			Both Lungs.		
	1st Stage.	2nd Stage.	3rd Stage.	1st Stage.	2nd Stage.	3rd Stage.	1st Stage.	2nd Stage.	3rd Stage.
Males	179	28	23	176	40	33	79	16	8
Females ..	112	27	15	146	29	31	48	6	4
Total	291	55	38	322	69	64	127	22	12
	384			455			161		

In these cases the left lung is shewn to be more frequently diseased than the right. In the first period the difference is so small, that it might be regarded as accidental, just as the position of tubercle in this respect, observed after death in Dr. Chambers's cases, appears to be accidental; but in the above table a gradually increasing excess, as the disease advances, is shewn on the part of the left lung, and Dr. Cotton concludes that this points to the great probability that tubercular softening and vomicae are more prone to happen on that side.

These recent statistics appear, then, to confirm the conclusion arrived at, that it is not yet proved that either lung is more prone to the deposit than the other. As remarked by Dr. Cotton, the point is not of the slightest practical value, either to the diagnosis or the treatment; but it is important to place it in its true light in reference to the actual state of science, for there can be little doubt that positive mischief has accrued under this head, by the premature deduction of a general law from the observation of a limited number of cases.

I turned with very considerable interest to the account given of cretaceous tubercle. In 2,161 autopsies, after death from all diseases, it was found in sixty-five cases, that is to say—

In twenty-nine, associated with tubercle in the lungs.

In three, with tubercular disease elsewhere.

In thirty-three, alone in the lungs.

The last thirty-three cases are not counted among the cases of tuberculosis; but the evidence is so strong for their tubercular origin, that Dr. Chambers questions whether they ought not to have been included. One proof is, that in twenty-six cases out of the thirty-three, the deposit was met with in the upper lobes; in two irregularly scattered; and in five in the lower lobes; a distribution improbable for lobular pneumonia. Its distribution among the sexes

was also similar to that of tubercle, which the author considers would be unlikely in two substances wholly unconnected, to which may be added the frequency with which it was found with tubercle in the same individual; and we can hardly fail to consider it, "almost in every case, a proof of the former existence of the morbid deposit."

I am glad to meet with this confirmation of an important conclusion arrived at from other evidence, since it has been objected, that too much reliance has been placed on this chalky deposit as a proof of the curability of tubercular disease in an organ.

Dr. Chambers gives five "*suppositions*" to account for the origin of the cretaceous matters, and maintains that there is nothing to render either of them untenable; a tolerably sure proof that we are in the dark upon the subject.

The cretaceous matter in the lungs was associated with tubercle in the following manner:—

Mixed up with tubercle, twenty-one times.

In the walls of vomicae, five times.

In one part of the lungs, with vomicae elsewhere, twice.

With tubercle in the opposite lung, twice.

With tubercle in other parts of the body, but not in the lungs, three times.

The proportion of cases in which cretaceous tubercle was found to the total number of autopsies, was as nearly as possible 3 per cent.

Nothing has excited more discussion than the question of the inflammatory complications of tubercle in the lungs; nor has anything, probably, had a more direct bearing on practice than the views generally entertained as to the nature and origin of the morbid deposits met with in connexion with tubercle. One of the most useful results of these statistics will be, especially when derived from various sources, so as to admit of being collated and compared, that they must add materially to our knowledge of the circumstances under which such complications occur, and also aid our investigations of the relations which subsist between tuberculosis and other diseases. The length to which this paper has extended renders it necessary to defer entering upon this part of the subject.

Dr. Chambers's papers contain numerous tables showing the relative frequency of tubercle in different organs, in either sex, and at various periods of life, with the deductions at which he has arrived. I consider that the author has done great service to the pathology of tuberculous diseases by placing these facts on record, and that their value will increase as science progresses. The exception I have taken to general deductions from the proportions observed in the larger divisions, as from the ratio of cases in the male to those in the female sex, (viz. that the author is working upon minute fractions of the total number, and without any certainty that the examples before him are, in all essential respects, representations of the mass,) induces me to pass over both the proportions and the deductions, where the numbers are still smaller. But in extracting some of the more salient points, and thus freely commenting upon them, I trust I shall succeed in directing the attention of others to the whole series. One object I have in view is, to point to the necessity of publishing periodically, not only the pathological observations made at St. George's Hospital, from which this series is derived, but those of every similar institution in the kingdom. The least thoughtful reader will also arrive at the conclusion that some conventional usage should be adopted, for the purpose of carrying out such statistics on a uniform and well considered plan and nomenclature. If this were accomplished, practical conclusions, founded on facts, would soon supplant conjectural opinions; and, at least in some parts of the science of medicine, we might hope to arrive at *axioms* upon which to found our reasonings.

Norfolk Crescent, Hyde Park, Nov. 1853.

LITHOTRITY: EXHIBITION OF CHLOROFORM.

By WILLIAM THOMAS BELL, Esq., M.R.C.S., formerly House Surgeon to the London Hospital.

JOSEPH RICHARDSON, aged 62, a sailor, came under my care in July 1853. He was of moderate stature; his complexion was sallow, his countenance haggard and care worn, and expressive of extreme pain; his hair was grey; his habits of late years had been extremely temperate; for the greater part of his life he had worked as a sailor, but lately for farmers in this neighbourhood. He dated the commencement of his symptoms from three years back. Within the last six or eight months, his symptoms had been extremely aggravated. He had constantly passed blood, and thick muco-purulent matter. He also had prolapsus ani; and for the last few months had been unable to ride in a chaise, or sit upon a chair for many minutes together. After walking a short distance, he would be seized with a constant desire to micturate, attended by great pain. The urine was alkaline, and strongly ammoniacal.

On sounding him, the stone gave the impression of being soft, and fitted for lithotritry, should the urgent symptoms yield to treatment. This consisted in the administration of the following remedies:—

R Sodæ carbonatis gr. x.
Misturæ acaciæ 3 ij.
Tincturæ hyoscyami ℞xv.
Aque puræ 3vj. M.

Fiat haustus cum spiritus ætheris nitrici ℞xx. sextis horis sumendus.

R Tincturæ opii gtt. xxx.
Spiritus ætheris nitrici gtt. xxv.
Misturæ camph. 3x. M.

Fiat haustus sedativus horâ somni sumendus.

Perfect rest in bed, with a light, nourishing, unstimulating diet, was enjoined. The bowels were freely opened daily. After persevering in these remedies for about ten days, his symptoms so far subsided, and the urine assumed a more healthy character, as to allow the operation to be performed on July 13. He suffered a good deal of pain during the operation, which continued to a trifling extent during the day. The stone was readily seized, and gave way freely under the lithotrite. The usual preliminaries were of course attended to prior to commencing the operation.

Forty-eight hours afterwards, he had a little fever, accompanied by lumbar pains, which soon passed off. He took barley-water *ad libitum*. During the night subsequent to the operation, he passed a large quantity of stone.

Three operations were performed after this; but the extreme excitement prior to and at the time of the operation, produced such violent spasmodic and uncontrollable action of the muscles in the neighbourhood of the bladder, together with those of the extremities, that the performance of the operation was almost impossible. Under these circumstances, we determined upon administering chloroform, to produce partial anæsthesia. It was accordingly administered by our assistant Mr. Pritchett. The fifth and following operations were thus performed under chloroform, which had the effect of keeping him quiet, though at the same time in a "partially" conscious state. In this way, the operations were rendered comparatively simple.

September 10, about ten weeks after the patient had first consulted my father and myself, we carefully sounded the bladder, and could not feel the slightest remnant of stone. His symptoms being entirely relieved, we determined upon sending him home.

Nov. 19th. His general health had so far recovered, that he was able to undertake a journey on foot of seven miles without inconvenience. Although a difficulty occasionally presents itself in perfectly emptying the bladder, this, I think, may be attributed more to an enlarged prostate than to remains of the stone.

REMARKS. This patient presented such aggravated symptoms, that it appeared almost impossible to perform

lithotriety, unless his urgent symptoms were allayed. He had a capacious urethra, with enlarged prostate; a greatly dilated and rugous bladder. One symptom in his case strongly indicated the existence of stone; viz. that of being able to feel the stone move from side to side as he turned in bed.

This case has been brought prominently before the profession, with a view of advocating more strongly the administration of chloroform; for without its aid the operation could not have been repeated so as to complete the cure. The great point in its favour is, that it is only required to be exhibited to the extent of producing "partial" anæsthesia; and, to the best of my belief, chloroform may be administered thus far without the least fear of fatal consequences. (This is an invaluable point in the reduction of dislocations in certain constitutions.) In this case nine operations were performed. The composition of the stone was triple phosphate of ammonia and magnesia; its weight was three drachms and a half.

The carbonate of soda relieved very much. It is a very valuable remedy in cases of stone; and is extensively used in such cases by the surgeons at the London Hospital.

Great Grimsby, Lincolnshire, November 12, 1853.

CASES OF CHOLERA, WITHOUT COMMENTS.

By JOHN GROVE, Esq.

CASE I. Edwin D., aged 14 years, went to bed in perfect health and spirits on the night of October 31st. At 4 A.M. November 1st, he was seized with an attack of diarrhoea. His first evacuation was so copious that (according to his own statement) it nearly filled the chamber utensil. He is errand boy to a druggist. He complained of bellyache and relaxation in the morning on going to shop. His master gave him a warm dose of rhubarb: after this a teaspoonful of paregoric. Being no better from these remedies, he gave him one ounce of Board of Health mixture; half to be taken immediately, and to be repeated at 2 P.M. if necessary. At 4½ P.M. the boy's mother applied at my surgery, saying that her son had been purging and vomiting all day, and was very bad. The evacuations, she said, were like water, only with white flakes; and he was suffering severe pains in his belly and legs.

I ordered that he should be kept warm by means of hot bottles to the body and extremities, and administered the sulphur mixture, with a small quantity of liquor opii sedativus.

At 6½ P.M. a messenger came to say he seemed somewhat better. Up to this time I had not seen the lad, in consequence of being required urgently in another direction.

At 8½ P.M. a messenger arrived to say that the lad was not so well. I went immediately to see him. He was perfectly pulseless; his countenance was sunken and livid; his lips were blue; he had dark areolæ around the eyes; his hands and feet were purple, and the skin shrunken. There was no sweat. The voice was peculiar, resembling the falsetto. He had vomited and was purged just before my arrival; both of these evacuations were like arrowroot or rice-water. He complained of cramps, and required his legs to be constantly rubbed. Thirst was urgent. He passed no urine. I administered the sulphur mixture, with two minims of liquor opii, and waited half an hour; I then gave him another dose at 9 P.M. These were both retained; but he was moved twice before I left, at 9½. Evacuations were the same.

At 10 P.M. a messenger came to say he had not vomited since I first saw him, but the bowels had been moved twice. I now allowed a small quantity of soda water; as he begged incessantly for cold water to drink.

11½ P.M. There had been no sickness since 8½ P.M. The bowels continued loose, the stools being the same in character. The mother had substituted a bed-pan instead of getting him out of bed, because the cramps were so severe when he was moved off the bed. The surface was now

much warmer; the pulse was perceptible at the wrist. The voice was slightly improved. The eyes were still as sunken, and the dark areolæ as pronounced as before. The spasms of the abdomen were not nearly so severe. He complained bitterly of thirst. I directed him to take sulphur mixture without opium every two hours. Soda water and arrowroot water cold, in limited quantities, were allowed as drink. The warm applications to the surface were continued.

Nov. 2, 6½ A.M. He had had a restless night, but slept at intervals. The bowels had been open four times. He was sick at 2 A.M., 4 A.M., and 6 A.M. I visited him at 8 o'clock. The countenance was somewhat improved. The dark areolæ remained. The cheeks were sunken, and the face pinched; still there was a more healthy hue on the skin. Pulse 80, weak. The skin was warm. He had continual sighing. The cramps were much less severe, and only occasional. The evacuations remained the same. The medicine was continued. During the night the medicine had not been administered as frequently nor in the doses ordered.

12½ noon. He had had no sickness since 9 A.M. The bowels continued relaxed. He had had short sleeps at intervals, the eyelids only half closed. His countenance was better. The surface was warm. He was restless; and had not passed any urine. He evacuated the bowels in his bed. His pulse was 108. Thirst continued.

3 P.M. He had been sick half an hour previously, rejecting the medicine. In other respects, he remained the same. Pulse 100.

7½ P.M. He had not been sick again; the bowels were still relaxed. His lips were now florid; yesterday at this time they were quite blue. Pulse 96. I ordered a table-spoonful of beef-tea to be taken occasionally.

10 P.M. The bowels had not been moved since 7½ P.M.; nor had he been sick. No urine had yet passed. He had taken beef-tea twice, and liked it much. He had dosed for short intervals more tranquilly, with the eyes closed. When awake, he tossed his arms about, and sighed very much. He was directed to continue the medicine every two hours.

Nov. 3, 6½ A.M. The father came to my house, bringing with him the first urine (3ij) which had been passed since Tuesday midday. An interval of thirty-six hours had elapsed; for this occurred at 12½ on Wednesday night. The bowels were still loose; there had been slight sickness once; and he had taken half a pint of beef-tea during the night.

9½ A.M. He lay on his side in a tranquil sleep, and had been so for three-quarters of an hour. The countenance was rather flushed. The dark areolæ of the eyes were subsiding. He had had one motion of the same character since 7 o'clock. Urine had been passed several times. Pulse 90. He was not roused by the manipulation. I left him asleep, after waiting thirty minutes, ordering a continuance of the medicine and beef-tea as before, with alum-whey *ad libitum*.

2 P.M. He continued much the same, but was very delirious two hours since, and could not be kept in bed.

9 P.M. The face was very flushed. The tongue, which had never presented any remarkable appearance, was now florid and dryish. He had slept two hours, with the exception of a few minutes, when he turned in bed. He had passed urine abundantly, and had but two motions since 2 P.M.: the last, though but slightly stained, had for the first time a fæculent odour. Pulse 80, of moderate strength. He complained of great exhaustion, and extreme soreness and weariness of extremities; also more or less of pain in the region of the stomach, of which he had complained at every visit I paid him. He vomited once, after too large a draught of whey. The medicine was ordered to be taken every four hours.

Nov. 4. The following is the history of the night of the 3rd, from the father's notes. He had a slight motion at 9½ P.M.; went to sleep at half past; awoke at 11, and had some whey. There was then slight wandering. He went to sleep at quarter to 12; and awoke at 1 A.M., and took medicine. He had a motion, much improved, at 1½ A.M.; he took some beef-tea; at 2½ A.M. he had a little soda water, then fell asleep, and slept till 4 A.M. He took a wineglass-

ful of beef-tea, fell asleep immediately, and slept till 5½ A.M. The bowels were moved; he took medicine; then dosed, and moved again at a quarter to 7 A.M. He did not ask for drink above once during the whole night.

11½ A.M. The countenance was improving. There were blotches on the cheeks like ecchymoses. Pulse 72. There was slight thirst and headache. The bowels were still loose. Urine was abundant. The pupils were natural.

9 P.M. He continued much the same. Pulse 72. The skin was not particularly hot; the tongue was clean. He complained of great soreness all over the body, and slight headache. He had slept at intervals during the day. He had had six motions since 11½ A.M. He had eaten a piece of biscuit, and a little toast soaked in beef-tea. The medicine, whey, beef-tea, etc., were continued.

Nov. 5, 9½ A.M. He had passed a very tolerable night, and had no wandering. He had had six motions since nine last night; they were now unequivocally tinged with bile. He complained of intense soreness and headache. The pupils were natural. The urine was abundant. Pulse 72. Tongue clean. Thirst moderate. A drachm of compound tincture of cinchona was ordered to be taken three times a day in water.

8 P.M. He had had six motions since my last visit. The pulse was still 72. The tongue was clean. The skin and head were cool. He had had some disposition to eat. He amused himself this afternoon by looking over some favourite books. Half a drachm of compound tincture of camphor was added to each dose of the bark.

Nov. 6. There was nothing worthy of remark, except that the evacuations had assumed a perfectly bilious appearance.

Nov. 7. He had a perfectly healthy stool to-day, and took a light nourishing diet with relish.

Nov. 12. He was gradually gaining strength.

On the 9th, a rose-coloured eruption made its appearance, which extended pretty generally all over the body, and declined on the fourth day. It had the appearance of typhoid fever eruption, as was also remarked by Dr. Cormack, who saw the case.*

CASE II. Charles D., aged 7, brother to preceding, had relaxed bowels all day on the 5th November, which the parents did not know until evening, when the child appeared very ill, and he told them he had been many times in the day. Having medicine in the house, his mother gave him a dose of sulphur mixture, and he went to bed at 9 P.M. He slept till three, when he had a call from the bowels, and was sick. He then took another dose of the sulphur mixture. In half an hour he fell asleep, and slept till 8 A.M. He was then again relaxed and sick.

At 10 A.M., Nov. 6, I was requested to visit him. His mother had dressed him; the little fellow was sitting in a chair, with his head reclining against its back. His lips and hands were livid and cold. The dark areolæ around his eyes were very pronounced. He had had a motion, and was sick just before I arrived. These evacuations were characteristic of the disease. He passed no urine.

I saw him at 1 P.M., and at 7 P.M. His urgent symptoms had abated. He was neither so sick nor so relaxed, but the evacuations were the same. He had severe pain in the abdominal region, but no cramps of the legs.

10 P.M. There was more general warmth of surface. The countenance was better; his bowels were now nearly quiet. He said he felt better, and that the pain in his belly was gone.

Nov. 7th. 9 A.M. He had had a very restless night, with delirium, constantly getting out of bed, and wanting to put on his clothes. He had rejected everything that he had taken during the night. At 5 A.M., he fell asleep, and slept till eight o'clock. He then had a dose of medicine, which he retained. His bowels had not been moved after my visit last night, until this morning. In this evacuation

there was a little colour. The first urine was passed this morning at 4 A.M.: he had not previously passed any for twenty hours. It amounted to about an ounce and a half, of sweet odour, and pale yellow colour.

5 P.M. He had been asleep nearly all day, and had no sickness. One feculent evacuation had passed.

Nov. 8th. He was nearly convalescent.

The father of these children was attacked suddenly with sickness and diarrhoea. He took a full dose of the medicine, and went immediately to bed. In a few hours, he rose perfectly well.

CASE III. Sarah C., aged 27, was perfectly well on Nov. 6th. At 3½ A.M., on Nov. 7th, she was seized with bowel complaint. She described her sensations as "a boiling in her inside". The bowels were relaxed a great many times on this morning. She went out for a walk, thinking it might do her good; and was out an hour and a half. When she returned, she was very giddy and relaxed. She went to bed at 7 P.M., and slept till eleven, when she was roused with pain and relaxation, and did not sleep after this. The bowels were relaxed all the night, without pain.

Nov. 8th. She continued relaxed all the day.

Nov. 9th. She could scarcely rise from her bed in the morning to attend to her children, as she felt so exhausted. At 9 A.M., she sent to a druggist for medicine. Before the messenger returned, she was very sick. The Board of Health mixture was sent. Every dose was rejected, and the bowels continued relaxed all day. The evacuations, as described, were quite characteristic.

At 3 P.M., she had severe pains in the shoulders, back, and chest, which came on like cramps. She had slight cramps in the legs.

The above is the history of the case before application was made to me, in part obtained subsequently from the woman herself, and in part from the messenger who came to my house at a quarter past five. This person said she was now very dark about her eyes; her lips were blue; she was cold; her feet and hands were blue and cold. She vomited and was purged at short intervals, and had cramps in her legs. I gave the sulphur mixture, and ordered a dose every quarter of an hour. In three hours and a half, the messenger returned, saying that the bowels had not been moved since the first dose of the medicine was taken, but the sickness continued. Her appearance was much improved; and, under the use of bottles of hot water, warmth had returned to the surface. I continued the medicine. I ordered the female attendant to report to me at half-past ten. She did not come.

Nov. 10th. 9 A.M. The attendant arrived, saying that the bowels had not been moved all night, but that the sickness was still distressing. In all other respects, the patient was better. I ordered a neutral effervescent mixture to be taken every quarter of an hour, and medicine to be continued every two hours.

I first visited her at 12½. She was lying in a very exhausted state, with a feeble pulse and sunken countenance. She had been sick but once since half-past nine, and said she felt considerably better. She had not passed any urine since 4 P.M. yesterday.

7 P.M. The sickness and diarrhoea had returned. She had passed about an ounce of urine. The evacuations from the bowels were faintly tinged.

9½ P.M. The messenger said that she was better. Ordered to continue the medicine.

Nov. 11th. 10 A.M. The sickness did not entirely leave her till eleven o'clock last night, when she fell asleep, and slept till 1 A.M. The bowels had been relaxed four times during the night, without pain. She was not so thirsty. The motions were improving. The urine was very small in quantity, and not more than an ounce during the night. She was now passing the most of her time in short snatches of sleep.

Nov. 12th. Noon. She was dosing comfortably. Her pulse was feeble, 90. Thirst was moderate; there was no sickness; the bowels had been moved; the evacuations were nearly natural in colour.

* Was not this a case of typhoid fever with the choleraic type? The designation of the case is, however, of little importance, as its history is so well and so fully given by Mr. Grove.—EDITOR.

Nov. 13th. She was in a very feeble state, but had no unfavourable symptoms.

Nov. 14th. She was taking bark, and getting on well.

NOTE. Many cases of diarrhoea, with and without vomiting, have occurred during the last six weeks, all of which have been treated by sulphur; in some few cases, a small quantity of opium has been administered in conjunction with the sulphur; but I am inclined to think, from a more extended experience, that it might be omitted altogether.

Some persons have doubted whether the cases reported as successfully treated by sulphur were true cases of cholera: the above histories, however, may possibly remove this doubt.

Wandsworth, Nov. 16th, 1853.

BIBLIOGRAPHICAL NOTICES.

ESSAI SUR L'EMPLOI MÉDICALE DE L'AIR COMPRIMÉ. Par le Docteur CH. G. PRAVAZ. pp. 377. Paris: 1850.

[MEDICAL USE OF COMPRESSED AIR. By Dr. C. G. PRAVAZ.]

IN the ASSOCIATION JOURNAL for September 9th, we inserted an interesting article by Mr. POYSER on the treatment of chronic and other diseases by baths of compressed air. We have now before us a work by the late Dr. PRAVAZ of Lyons, in which the subject is more fully discussed.

The first chapter contains some preliminary observations on the mechanism of respiration in relation to atmospheric pressure. From his own observations, and those of other writers, the author concludes—

1. That the extent of forced inspiration or the development of the lung increases with the pressure of the atmosphere, up to a certain limit, which in general seems to be determined by the vigour of the individual.

2. Atmospheric pressure ceases to favour the expansion of the respiratory organs, when it begins to exceed the constantly decreasing difference which exists between the efforts of the inspiratory muscles and the elasticity of the walls of the thorax.

In the second and third chapters, the influence of atmospheric pressure on the chemical and physiological phenomena of respiration, and on the circulation, are examined.

In chapter fourth, the author examines the nature of the physiological phenomena observed in the ascent of high mountains, and in balloon ascents. Dr. Pravaz passes in review the observations of Dacosta (who, in the fifteenth century, was the first to apply the name of *mal des montagnes* to the affection under consideration), Bouguer, Saussure, Sherwill, Clarke, Rey, Pidwell, Mlle. d'Angeville, MM. Bravais, Martins, and Lepileur, Humboldt and Bonpland, Boussingault and Colonel Hall, Gérard, Blanchard, etc. We translate from this chapter the author's conclusions as to the cause of the affection. They may be compared with those of Dr. Speer, given in his paper on "Mountain Sickness", published in this Journal for January 21st and 28th.

"Dr. Brachet has very well explained the breathlessness and absolute exhaustion which are experienced after the least effort in a highly rarefied atmosphere. . . . According to the view of Liebig, an immediate consequence of the production of muscular action is, that a part of the muscular substance loses its vital properties, and is detached from the organ. At the same time that it undergoes this change, it fixes oxygen, and is then eliminated from the system in the form of carbonised or azotised compounds. The condition necessary for the continuance of the muscular efforts is then the introduction of a sufficient quantity of oxygen into the system. If this element is deficient through rarefaction of the atmosphere, the oxidation of the metamorphosed tissues is impeded, and the metamorphosis itself is arrested; rest alone, by accumulating in the organism, notwithstanding the imperfect respiration, a proper quantity of the eliminative gas, can re-establish the essential condition for the exhibition of the muscular force. This is what is observed in the ascent of high mountains, where it is sufficient to rest for some minutes to recover the power of proceeding, when this power has seemed entirely lost.

"Sometimes the necessity of furnishing to the system a sufficient quantity of oxygen, in order to maintain voluntary and involuntary motion, and the cerebral functions, is not satisfied by rest. Sleep then seizes on individuals who are plunged in a very rarefied atmosphere; and it may be considered as a resource of the conservative power of life, to reserve the small quantity of oxygen absorbed, for the production exclusively of the movements of the heart and chest, without which life would soon cease.

"There is a symptom of mountain-sickness which, under all latitudes and at different temperatures, appears more constant than others, and increases in tolerably exact proportion with the altitude which is arrived at. It is the congestion of the mucous membrane of the mouth, nostrils, and eyes, and of the brain.

"This will be understood when we reflect that one of the exciting forces of the circulation in the veins, and therefore in the capillaries, decreases in proportion as we are elevated above the level of the sea. The higher the altitude we reach, the less actively the blood will be attracted towards the right cavities of the heart, and the more will this fluid tend to engorge parts where the respiratory act is most commonly felt most powerfully. . . .

"The force of impulsion of the left ventricle, and the greater calibre of the arteries ascending to the head, are the only individual circumstances which may cause, at equal altitudes, a variation in the tendency to hæmorrhages and to apoplexy, which is produced in high mountains by the weakening of one of the powers which concur in bringing back the venous blood to the central organ of circulation.

"Mountain sickness presents another symptom whose frequency appears to be also in proportion to the altitude; for it is especially in the ascent of the Cordilleras and Himalaya that it is observed. This symptom, which no one has hitherto attempted to explain on physiological grounds, is manifestly produced by an impediment to the circulation in the portal venous system: it is characterised, in fact, like congestion of the liver and abdominal viscera, by vomiting, cramps of the stomach, and intestinal pains." (pp. 80-3.)

In chapter fifth, we find a consideration of the physiological effects produced by the condensation of the atmosphere. The construction of the diving-bell is intimately connected with this subject; and we hence find reference to the diving-bells of Sturmius, Halley, and Spalding, and a copy of a letter addressed by Dr. Hamel to Professor Pictet of Geneva, giving an account of a descent in a diving-machine near Dublin.

The results of condensed air in mines and in the diving-bell have so far been considered only as accidental results; but, in 1783, the Society of Sciences at Haarlem proposed the following questions:—

- "1. Describe the apparatus most fitted for making experiments on condensed air in the most convenient and certain manner.

- "2. Examine, by means of this apparatus, the action of condensed air in different cases; for example, on animal life, on the growth of plants, and on the inflammability of different kinds of air."

Dr. Pravaz observes that no practical answer had for many years been given to these questions:

"It is only in late years that the solution of the questions proposed more than sixty years ago, has been perseveringly followed out; and it is to Dr. Junod that we are indebted for taking the true initiative in these researches."

In a memoir on the effects of the condensation of the air on a healthy man, presented to the Academy of Sciences in 1834, Dr. Junod wrote:

"When the natural pressure of the atmosphere is increased by one-half, the following phenomena are observed. The membrana tympani being pressed towards the internal ear, becomes the seat of an uncomfortable sense of pressure, which is however gradually dissipated as the equilibrium is re-established, probably by the introduction of the condensed air into the cavity of the tympanum through the Eustachian tube. The respiratory act is performed with new facility, the capacity of the lungs for air seems to be increased, and the inspirations are deeper and less frequent than ordinary. At the end of a quarter of an hour, an agreeable heat is felt in the interior of the chest. The circulation appears to be modified; the pulse is frequent and full, and is compressed with difficulty; the calibre of the vessels

ficial vessels is diminished, and may even be completely effaced, that the blood, in returning to the heart, follows the course of the deep-seated veins. The intellectual faculties are excited; the imagination is lively; the thoughts are accompanied with peculiar pleasure; and, in some persons, a sort of delirium or intoxication is manifested. The muscular system partakes in this increase of activity; the movements are easy and energetic, and appear more certain. The functions of digestion and secretion (especially of the saliva and urine) are performed with ease. One would say that the weight of the body is sensibly diminished; at least, such is the sensation experienced by a person shut up in a condensing apparatus."

It appears that the merit of first applying condensed air in the treatment of disease is due to Dr. Junod. The rest of the chapter is occupied with a discussion of the different results obtained when the whole body is immersed in a bath of condensed air, and when only a part is so treated; and with a brief description of the physiological effects of the compressed air-bath.

Chapters six to fifteen are devoted to a description of the treatment of the following diseases by compressed air: phthisis in the first and second stages; Pott's disease, and certain diseases of the hip-joint; rickets; deformities of the spine and chest (as a preventive, or rather tardative, in the early stage); chlorosis and anæmia; different kinds of deafness; chronic congestion of the brain and spinal cord; dyspepsia, and other affections connected with the pneumogastric nerve; and poisons, either introduced from without or generated within the body.

The paper of Mr. Poyser, to which we have referred, renders it unnecessary for us to dwell longer on this subject. We would only recommend the work of Dr. Pravaz to the attention of those who may be desirous of examining for themselves the efficacy of the plan of treatment which it advocates.

PATHOLOGICAL AND PRACTICAL TREATISE ON EPIDEMIC CHOLERA: ITS HISTORY, CAUSES, VARIOUS FORMS, AND TREATMENT. By O'B. MAHONEY. pp. 190. London: 1853.

The author had extensive experience of cholera in Ireland, during the epidemics of 1832 and 1849; and has thus been enabled to make a useful contribution to our knowledge of the disease. The principal topics considered are: 1, the history and exciting cause of epidemic cholera; 2, its proximate cause and pathological effects; 3, its predisposing cause; 4, its definition; 5, its symptoms; 6, its prognosis; 7, the appearances after death; 8, the treatment; 9, illustrative cases; and 10, means of prevention.

Passing over the pages devoted to the history and pathology of cholera, we arrive at the author's definition of the disease, which is as follows:

"**DEFINITION OF EPIDEMIC CHOLERA.** Vomiting and purging of sero-lymphous matter; spasms or cramps of the muscular fibres, particularly the muscles of the extremities; general prostration of the vital energies; universal collapse. After a few hours' reaction, or insensibility, coma, and death."

The account given of the appearances of the body after death is not of much value, as no notice is taken of the diversity of appearances caused by the diversity of the stage of the disease in which the patient has died. One general description is given as applicable to what is to be seen in the bodies of all cholera patients.

The most interesting part of the volume is that in which the treatment is considered. The observations on this subject are arranged so as to apply to the different stages of the disease, which are designated: 1st, choleraic invasion; 2nd, cholera; 3rd, cholera with collapse; and 4th, the sequelæ of cholera. It is judiciously remarked:

"Cholera is a continued series of morbid conditions constituted of distinct phases, each well characterised by definite symptoms, and requiring, according to certain associations of circumstances, frequently opposite modes of treatment. A search after specific remedies would therefore only give evident indications of a reckless intrepidity, totally incompatible with a just estimate of professional character, and of a woeful lack of a

due regard to the safety of the community. It is well known to those who steadily addict themselves to the pursuit of truth in any line of thought, that disturbance and disappointment frequently arise, notwithstanding their utmost efforts to the contrary, from the incessant intermixture of erroneous ideas allied to the subject of which the mind is labouring to make itself master, and which take them from the principle of mental association: therefore it is of the first importance in the investigation of cholera to exclude altogether the notion of a specific, and to steadily keep before our mind that this disease must be subject to the same laws of pathological inquiry as are applicable to every other malady, the peculiar characteristics of cholera consisting in the intense severity of the symptoms, and in the rapidity with which the morbid changes occur." (pp. 131-2.)

We cannot sanction the author's use of the lancet in the first stage—or in any stage—of cholera, even though the practice is only recommended for "robust persons with a full and frequent pulse".

The following passage seems a fair specimen of the sort of facts upon which calomel in large doses is recommended.

"It is generally conceded, that calomel and opium in conjunction best assist in restoring the healthy functions of the several organs. This combination, in the proportion of five grains to one, ten to two, or even fifteen to three grains of opium, may now be administered, and repeated if the first dose be rejected, or if otherwise necessary. The efficacy in this stage of two grains of opium and ten of calomel is positively great, when preceded by turpentine frictions, etc., and immediately followed up by an enema composed of ol. terebinth. ʒij; ol. olivar. ʒj; aq. calid. ʒiss." (p. 81.)

We feel thoroughly satisfied in our own minds that the turpentine frictions and turpentine enema may be trusted to without the five or fifteen grains of calomel, and we believe the opium may be generally used much more sparingly.

Turpentine and creasote are favourite remedies with Mr. Mahoney in cholera; and at this we are not surprised, for they have only to be fairly tried to be found reliable in most cases. Calomel is always kept in view by Mr. Mahoney; and this drug is constantly getting the credit of what seems to be clearly due to other medicines, particularly to creasote and turpentine. To arrest the serous discharges, he chiefly seems to prescribe this mixture—

R Creasoti, et
Acid. acet. ʒij.
Sp. vini rect. ʒss. M. f. solutio.

Speaking of this solution, he says:

"From eight to twenty drops may be given in an ounce of any aromatic water, or of camphor mixture, every two hours or after each time the patient vomits."

"Every one must be aware of the difficulty sometimes experienced in allaying the violence of the sudden vomiting without nausea, of cholera patients, which so rapidly prostrates the strength. This solution of creasote and acetic acid, as we have observed above, admirably fulfils this indication; it excites no nausea, nor any other unpleasant symptom. Its action seems to be moderately excitant, antispasmodic, sedative, and perhaps styptic, allaying the burning sensation at the epigastrium, imparting an agreeable feeling of warmth in the stomach and bowels of the patient, and restraining the mucous surfaces; thus checking simultaneously both the vomiting and purging. That it acts directly as an astringent we are not prepared to affirm; but that it operates with efficacy in arresting the sero-albuminous discharges, poured out upon the mucous surfaces of the alimentary canal, we do not entertain the remotest doubt. We have, in short, repeatedly successfully treated cases of this type or stage of the epidemic with the creasote and acid solution, after one full dose of calomel and opium; but more frequently we have applied the terebinthine appliances conjointly." (pp. 90-91.)

Tannin, matico, nitric acid, acetate of lead, nitrate of silver, and various other medicines were prescribed by the author under particular circumstances. Without entering into details, we give the formulæ of two mixtures which he used in cholera.

R Decoct. matico ʒviij.
Pulv. tanninæ gr. xij.
Tinct. opii ʒj.

Vel

Rx Acidi nitrici dil. ʒij.
Mist. camph. ʒviii.
Tinct. opii ʒj.

One ounce of these mixtures, it is stated, may be taken every third hour.

Speaking of *cholera with collapse*, he advises calomel, but not in the poisonous doses advocated by some authors. Calomel, opium, and assafœtida, is a favourite combination. He says,

"When the constitutional effects of mercury were produced on a patient subjected to the mode of treatment detailed, we had remarked that rapid convalescence usually followed. Should diarrhœa precede the attack, and if the serous fluid be passing in quantity from the bowels of the patient, notwithstanding the employment of the terebinthine enemata,—the creasote solution, the full dose of calomel and opium, and the counter-irritations,—the enema ought to be repeated, with the addition to it of one drachm of tincture of opium; and the following powders substituted for the pills of calomel, opium, and assafœtida, if cramps be absent:

Rx Chlor. hydrarg. gr. ij.
Ext. opii gr. 4.
Pulv. tanninæ gr. iij.
" aromat. gr. iv. M. F. pulvis."

Four of these powders are to be made up; and one is to be given every second hour in some aromatic water, with six or eight drops of the creasote solution already described. Mr. Mahoney prefers these powders "for many reasons to acetate of lead": but he says,—

"Acetate of lead, when administered in large doses, in combination with opium and acetic acid, is sometimes of use in the cases just indicated. We have tried acetate of lead in scruple doses, dissolved in distilled vinegar as enemata, with some advantage in these cases; but prefer the terebinthine preparations." (pp. 99, 100.)

Nitrate of silver is thus mentioned:

"When there has been reason to apprehend the presence of ulceration low down in the colon and rectum, which is indicated by a feeling of pain or uneasiness referred to the part, the evacuations from the bowels being sudden and impetuous, we have used enemata composed of from six to twelve grains of nitrate of silver dissolved in four fluid ounces of distilled water, with seemingly considerable advantage. Should the pain be aggravated by this, it will be desirable to follow it immediately with an emollient or an opiate enema." (p. 126.)

To review thoroughly this little volume would be to write a treatise on cholera. We will, therefore, only say that in the glance which we have taken at it, we have not been able to do as much justice to the author as we could have wished. His experience is instructively communicated; and the volume is one which cannot be perused without profit.

PERISCOPIC REVIEW.

TOXICOLOGY.

POISONING BY ACONITE: RECOVERY.

Dr. PUTNAM stated the following case on February 14th, 1853, to the Boston Society for Medical Improvement. It is thus reported in the *American Journal of the Medical Sciences* for July, p. 69.

"The patient swallowed by mistake, a teaspoonful of the saturated tincture of aconite at seven, A.M. Not being fully aware of the danger, she merely took a seidlitz powder. In fifteen minutes, she had retching and burning pain in the stomach. Ipecacuanha was immediately administered, by which she was freely vomited. The skin was at this time cold: the pulse was 100, feeble, and regular: the fingers were spasmodically extended: convulsions of the whole body were frequent, but of short duration: the mind was not particularly affected. Friction with ammonia, mustard, etc., were assiduously employed, and copious draughts of arrow root, with occasionally brandy and water, and spirits of sulphuric ether, were given. Three hours afterwards, she continued to complain of burning pain in the stomach and bowels, (but it was not so severe,) of pain in the throat, thorax, and lower part of the spine. She

had almost incessant retching and spitting, irregular and spasmodic respiration, and the pulse feeble, 120, intermitting after every second stroke. She had just had one general convulsion, lasting about five minutes, and there were frequent slight spasms of various parts, especially of the fingers. The pupils were dilated, but contractile on exposure to strong light. The mind was clear. Tinct. opii ℥xx were prescribed to be given occasionally. Immediately after taking the laudanum she became more comfortable; the spasms and other symptoms being less severe. At night, the symptoms had become regular, and on the next day she was apparently well."

FATAL POISONING BY ACONITE ROOT TAKEN IN MISTAKE FOR HORSE RADISH.

About a fortnight ago, an inquest took place at Bristol, in a case of the above description. We copy the following account from the *Times*.

"Some time since, Mr. Joseph Russell, a wine merchant at Bristol, died, bequeathing, among other legacies, one to a distant relative, named also Joseph Russell, a bookseller, residing at Chard, Somersetshire, and who during the past week came to Bristol respecting it. On Sunday last [8th Nov.] he dined with one of his brothers, a coachmaker resident in Bristol, and he partook of some roast beef, he at the time being in excellent health. He remarked that roast beef was nothing without horseradish, and his brother's wife stated that there were some horseradish roots in the garden, and the servant was sent to dig up one. The root was scraped in the usual manner, dressed with vinegar, and placed on the table; both his brother and the deceased partook of it, but said at the time it must be very bad horseradish, as it did not possess the usual flavour. Mrs. William Russell, disliking horseradish, did not partake of it. Soon after dinner, Joseph Russell complained of a peculiar tingling sensation in his hand and arms, and this feeling rapidly increased till he said he felt it creeping round his neck. His brother replied, "Oh, perhaps the dinner has disagreed with you; let us take a walk and you will be better." They accordingly went towards Hillgrove-street, where the third brother resided, and on the way the brother William complained of a similar sensation, though in a slighter degree. The symptoms in Joseph became more alarming, and, on reaching his brother's house, he sank into a chair, exclaiming, "I am poisoned, for I feel one side of me dead already." Brandy was given him, and medical aid instantly procured, but he rapidly sank, and died in about an hour afterwards. The other brother, who had taken much less of the supposed horseradish, was much affected, but is now recovering. On an examination it was found the root was the *aconitum napellus*, wolf's-bane, or monk's-hood, which, particularly at this season of the year, strongly resembles horseradish, but which is a strong narcotic poison. An inquest has since been held upon the body of the deceased, and a verdict was returned of "Died of strong narcotic poison, *aconitum napellus*, taken in mistake for horseradish."

FOUR GRAINS OF EXTRACT OF BELLADONNA, AND FOUR GRAINS OF OPIUM, SWALLOWED WITHOUT DETRIMENT BY A CHILD NINE YEARS OLD.

A case of which the above is a summary, reported by Dr. COALE, is given by the *American Journal of the Medical Sciences* for July, p. 69.

"The child swallowed two suppositories, each containing two grains of the above mentioned narcotics. It went to sleep not long after: the mother awoke it at the end of four hours with much difficulty, when very free vomiting ensued, producing great exhaustion. The drugs were taken at noon, and at seven P.M., the child seemed only a little fatigued and sleepy. It had eaten dinner immediately before swallowing the poison, and Dr. Coale suggests that this may have retarded absorption."

MATERIA MEDICA, PHARMACY, AND THERAPEUTICS.

NEW METHOD OF ADMINISTERING SULPHATE OF QUININE.

In the *Revue Médico-Chirurgicale*, for September 1853, we find a notice of an article by Dr. BERTELLA on a new method of administering sulphate of quinine. This plan consists in combining with the quinine an equal quantity of tartaric acid, which has the effect of not decomposing the salt, but of rendering it more soluble, and of causing absorption to take place more readily. He gives at a dose three grains of disulphate of quinine and three of tartaric acid. The dose at the commencement is from six to twelve grains of each.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, NOVEMBER 8TH, 1853.

JAMES COPLAND, M.D., F.R.S., President, in the Chair.

PRESIDENT'S ADDRESS.

The PRESIDENT, on taking the chair, congratulated the society on the commencement of this its fiftieth session, and on the publication of the thirty-sixth volume of the *Transactions*. He trusted that during the ensuing session the more experienced fellows of the society would still give their countenance and support to the meetings, and enter into the discussions which often formed a very important part of their proceedings. He had hoped that early in the session, a sufficient number of papers would be sent in to engage the attention of the society, but he regretted to say that so few had been received, that it was necessary that he himself should introduce one on the present occasion. In a society like this, holding justly so high a position in the estimation of the public and the profession, second to none in usefulness, and only to one in rank and age, it was, in his opinion, most desirable that all expressions of approbation or disapprobation on the reading of a paper, or on the observations made, should be avoided. They should be received with respect; but without any outward expression.

CERTAIN PATHOLOGICAL STATES OF THE BLOOD, ESPECIALLY CHARACTERISING MANY DANGEROUS DISEASES.

BY JAMES COPLAND, M.D., F.R.S., PRESIDENT.

The author observed that the alteration of the blood in severe and malignant forms of disease had been discussed by him in his work on *Practical Medicine*, more particularly under the heads of Abscess, Absorption, Blood, of the Causes and Pathology of Disease, etc., and his views of the morbid changes in these disorders had been long before the profession; but he thought, by bringing them before the society in a more practical and connected form, he might direct attention to matters of great importance in relation to the sources of contamination, and the channels through which poisons passed into the blood. The morbid state to which he more particularly directed attention might be termed contamination or vitiation, according as the causes might be external or internal: external agents and influences, as well as internal vital and functional changes, might equally be the sources of this vitiation, or both might co-operate. If a cursory view of the sources of vitiation or contamination of the blood were taken, they would be found to be numerous, varied, and often associated, and to infect or invade the blood by one or more channels.

These morbid states of the blood might arise—*First*, from causes acting on the digestive canal, and the vessels proceeding from this canal; *secondly*, from agents taken in by respiratory action, and through the respiratory surface; *thirdly*, from causes acting upon any part of the external surface or any tissue or part of the frame; *fourthly*, from the arrest or from the impeded or imperfect performance of any depurating or eliminating function; *fifthly*, from the passage of any morbid purulent secretion or excretion into the circulating mass; and, *sixthly*, from the conditions of vital influence, or the organic venous power endowing the heart and bloodvessels, and from the reciprocating influence exerted by the vascular system, and the hæmato-globulin circulating through the system.

Illustrations were given of the operations of the several causes of contamination passing through these channels. The effects of various kinds of food; emanations from numerous sources of pollution; air vitiated by overcrowding; absorption by an abraded, punctured, or incised wound; the passage of sanious, puriform, or other morbid matters, into the circulating current; defective action in, and imperfect discharge of, the several depurating functions, so necessary to the preservation of a healthy state of the blood; and, lastly, influences or agents, extrinsic or intrinsic, which either excite or depress the organic nervous system, reacting on the vascular system, and changing the blood circulating in it. The author adverted at some length to the operation of these conditions on the blood itself, manifested by a destruction or waste of the hæmatoglobulin or red corpuscles. He believed that these changes consisted—*first*, in a metamorphosis of the globules, or a partial vital conversion or decomposition of them; *secondly*, in a portion of the globules or hæmatoglobulin being converted into bile; *thirdly*, by the epithelial cells thrown off by the several emunctories, especially the kidneys, skin, and intestinal mucous follicles, being trans-

formed blood-globules; and, *fourthly*, that they are also partly expended in the elaboration of the genital secretions in both sexes. These were the chief modes or sources of waste. Having referred to Dr. Simon's arrangement and nomenclature of blood diseases, the author passed in review some of the more remarkable and characteristic conditions of malignant diseases arising from blood contamination, and concluded by relating cases in illustration of these conditions.

Mr. STATHAM hoped that the society might hear something more definite as to the meaning which the author gave to the word sanies, and hear how it was absorbed into the system, whether by the lymphatics or by what vessels? Was the pus which we sometimes saw in large quantities in abscesses in the viscera, and which became afterwards absorbed, the same kind of matter as that which produced fever, etc., when it got into the circulation?

Dr. COPLAND replied, that sanies was a generic term which denoted pus in an altered condition, or a depraved secretion from an ulcerated surface. When the ulcer had lost its power of resisting the imbibition of the discharge, this was conveyed into the circulation rather, he thought, by the veins than the lymphatics, and disease was the result. He could not refer to the microscopic characters of the sanious matter to which he referred, but it was a contaminated discharge, and not consisting of healthy pus-globules. It was found in dissection wounds, foul ulcers, etc. Treatment was indicated in the early stages by the appearances which the discharge assumed.

Mr. HOLMES COOTE inquired, what proof we had of what was called purulent infection of the blood. Looking at the fact that observers had failed with the microscope to determine with certainty the nature of the globules found in the blood in these cases, he questioned whether we were correct in assuming that these bodies were really pus-globules. It had, on the contrary, been shown that a portion of a diseased organ might be removed and taken into the circulation, and this independent of what was called purulent infection.

Dr. COPLAND had said that pus had been found in the blood of inflamed veins, but not in the vena cava or right side of the heart; that pus in a changed state introduced into the circulation was carried to the capillaries, and gave rise to the formation of matter in various parts; and that pus was not detected in the blood as pus. He would therefore yield upon the point of the presence of absolute pus in the blood having been proved. In these cases, the pus was changed and the blood was changed. It was not common for large collections of matter, as had been remarked by Mr. Statham, in the liver or other organs, to be carried out of the system by absorption. He had seen such cases, however, and they were not inconsistent with his views; but these cases were very rare, and only occurred when the powers of the system were supported, and the eliminating processes facilitated and encouraged.

[This being a ballot night, and the first meeting of the session, the rooms were crowded.]

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

SESSION XXXIII. FIRST MEETING.

WEDNESDAY, NOVEMBER 16TH, 1853.

JAMES Y. SIMPSON, M.D., President, in the Chair.

ON PEDUNCULATED EXOSTOSIS OF THE LONG BONES.

BY JAMES SYME, ESQ.

Mr. SYME remarked upon the loose and ambiguous manner in which the term exostosis had been employed by authors, and the consequent confusion in which the subject was involved. The opinion which Sir Astley Cooper had hazarded as to the origin of the disease in long bones, that it was due to excessive muscular action, he considered was sufficiently met by the two facts—*first*, that, as in the femur, the exostosis is found by the side of the tendon; and *secondly*, that it occurs on the distal phalanx of the great toe, where such a cause cannot exist. In young people, the tuberosities of the long bones are frequently enlarged, and occasion much alarm. Mr. Syme, in such cases, finds that symmetry is ultimately restored, and advises non-interference. In his opinion, the occurrence of such cases accounts for a large amount of the so-called orthopædic successes. The ordinary exostosis is not unlimited in growth; but, after a certain increase, it is found to remain stationary. A member of the profession, many years ago, presented himself to Mr. Syme, labouring under what he imagined was subclavian aneurism. Mr. Syme, on making the necessary examination, at once recognised the disease to be an exostosis of the first rib, situated close to the insertion of the scalenus anticus muscle. The subsequent history of this patient showed that the disease

did not increase in size. A lady of rank consulted Mr. Syme for a tumour growing into the pharynx, and expressed her wish to have it removed; but, as the tumour presented all the characters of an exostosis, and, from the history, had evidently reached its entire growth, Mr. Syme recommended non-interference.

As to the structure of ordinary exostosis, it presents a thin osseous lamina externally, and cancellated tissue within. It is sometimes covered by a thin coating of cartilage. Sir Astley Cooper's definition of this form of exostosis is very defective, and might apply to any bone of the body; and he includes under it two very dissimilar diseases, viz., simple exostosis, and the fibro-cartilaginous tumour of bone. Mr. Syme regretted to find Mr. Paget, in his lately published *Lectures*, making the same mistake. The two diseases differ *structurally*; the first presenting a simple bony texture, tipped with cartilage; the second, a cartilaginous matrix, with a bony shell. *Pathologically*, they differ: in the first, there is no tendency to increase, while no limitation can be placed to the growth of the second. Lastly, they differ *practically*. While the first may be successfully removed by the division of its neck, the second can only be extirpated by taking away the whole of the affected bone, or by section at a distance from the disease. Mr. Liston failed to make this distinction, and hence recommended amputation in the case of exostosis of the distal phalanx of the great toe—a practice which was always reprobated by Mr. Syme, and is now abandoned by the profession. With regard to the occurrence of the second form of disease in the upper jaw, Mr. Syme early saw the folly of attempting to dig it out piecemeal, instead of removing the whole bone. And as to the priority of having performed this operation, and any merit which might depend thereon, he would merely state, in passing, that he performed it on the 15th of May, 1829; and that an account of the operation appeared in the July number of the *Edinburgh Journal* of the same year. This fact seems to have escaped most authors of students' books, among whom he might mention Mr. Erichsen as the latest. In the case of the humerus, where this fibro-cartilaginous growth is of most frequent occurrence, Mr. Syme had many years ago removed successfully the entire arm for a growth of this kind, which was one of the largest on record. In another patient, where the tumour arose by a neck from the middle of the bone, and was about the size of an orange, the portion of the shaft from which the tumour sprang was included within two incisions, and the whole disease was removed. By the use of leather splints, the use of the forearm was in a great measure preserved.

To avoid confusion, Mr. Syme was of opinion that tumours formed by bone being developed around serous cysts, abscesses, etc., etc., should be named from the causes occasioning the growth.

The disease which formed the especial subject of this paper was most frequently met with on the inner side of the thigh, above the condyle, and at the neck of the humerus. Its neck varied from half an inch to an inch in length, and was always placed obliquely to the shaft. The tumour itself was nodulated, covered with cartilage, and of a pearly lustre, and had no communication with the surrounding parts. In a case which Mr. Syme had met with, where the exostosis was situated on the outside of the femur, similar characters were presented. About twenty years ago, Mr. Syme was consulted by a gentleman who presented an example of the disease in question. He recommended avoidance of violent exertion, and learnt from time to time that the tumour remained stationary. In February 1851, Mr. Syme was requested by Dr. Handyside to see his old patient, and found a very decided change. There was swelling and deep seated fluctuation. A cautious prognosis was given. Rest and a blister, to be followed by gentle pressure, were ordered; and the result was looked forward to with some anxiety. In a short time, all the untoward symptoms disappeared, and the exostosis was found to be in its original state. Another case, which fell under Mr. Syme's observation not long after, sufficiently explained these anomalous symptoms. A servant girl, in crossing from Fife to enter the hospital for the same disease, received a blow, which fractured the neck of the tumour, and detached it. Fearing suppuration, Mr. Syme cut down upon the loose exostosis, and found it lying in a bag of serum. On examination, all was explained; a synovial membrane covered the tumour, and was reflected in the form of a cyst, so that a double covering existed; and in the present case, from the violence applied, serum had been poured out between the layers. The other day, in company with Professor Simpson, he had seen a young lady who had suffered much agony from an exostosis on the inner surface of the neck of the

humerus, pressing upon the axillary plexus. From its situation, it had been deemed incapable of removal; but, on careful examination, Mr. Syme found that its origin could be traced by a narrow neck to the outer and back part of the arm, and, by an incision between the deltoid and the triceps, he was enabled to divide the neck by means of cutting-pliers, and successfully to remove the tumour. In conclusion, Mr. Syme called upon Mr. Lister to read an account of its microscopic examination.

Mr. LISTER here gave a very detailed and lengthened account of the microscopic appearances, which was not easily followed.

Professor MILLER was of opinion that Sir Astley Cooper's classification was not so far wrong; and he certainly thought that the one proposed by Mr. Syme was liable to equal misconception, from its including various kinds of tumours. Mr. Syme had mentioned their division into solid, hollow, and spicular; but under the solid would fall to be included the osteo-sarcoma and the osteo-cephaloma; under the hollow, abscess of bone and spina ventosa; and as to the spicular variety, a specimen had never fallen under his notice. Mr. Miller frankly confessed Mr. Liston's error in regard to the treatment of exostosis of the big toe, but only so far as Mr. Miller had had occasion to see the disease removed again and again on its reproduction; and, in his opinion, this reiterated operation was about as bad as amputation.

As to the priority claimed by Mr. Syme in the performance of ablation of the upper jaw, as a writer of students' books, (a title of which he was in no ways ashamed,) he had always done Mr. Syme justice; but he begged to remind the society that another individual claimed the merit of having first proposed the operation, and that, in Mr. Miller's opinion, was no small matter.

With regard to enchondroma, he had always taught that there were two varieties. One growing from the surface, and admitting of easy removal; the other internal, being developed in the interior of the bone. Of course, the practice differed widely in these two cases.

As to Mr. Syme's statement, that a synovial membrane covered the ordinary exostosis of long bones, he denied the fact of its being a synovial membrane at all. As in the case of other growths, the development of a serous cyst externally was of frequent occurrence; and, as was to be expected, an accumulation of serum took place from any exciting cause. This was no new discovery. Mr. Miller had always described it, and taught it to his students.

Professor BENNETT thought, that a greater similarity existed between the two varieties of tumour than had been acknowledged in the discussion. Their origin was the same. Cartilage was first formed, and subsequently underwent its usual ossific change. In his opinion, the only point of difference was in their seat: the internal and external surfaces of the bone being respectively affected.

The meeting separated after some further conversation, in which Professors Syme, Miller, and Bennett, Mr. Lister, and Dr. Cobbold took part.

EDITOR'S LETTER BOX.

MEDICAL STUDENTS.

LETTER TO THE EDITOR FROM GOLDING BIRD, M.D., F.R.S.

"No man careth for the student of medicine."—ASSOCIATION MEDICAL JOURNAL, p. 1008.

SIR,—Few, who are in any way conversant with the position of the medical student, when attending his duties at the hospitals and schools, could read the letter of "A Medical Student", contained in your last number, without some emotion. It is true that, as a class, they are too generally calumniated by the public, who know nothing of them. Too generally is it supposed that to be engaged in "walking the hospitals" is synonymous with being guilty of every kind of open vice and moral depravity. From an intimate knowledge of the habits and characters of the students of the large school of medicine to which I was for more than twenty years attached, I can bear witness to the many bright exceptions to this supposed general rule. Indeed, the comparatively small number who fell into habits of open vice or serious immorality was really remarkable, when, as is truly stated in the letter which has elicited these remarks, the student is surrounded by most of those temptations into which youth, when unguarded by higher principles, is too prone to fall. That a great change has, during the last ten years,

occurred in the habits and characters of all medical students, is a well known fact. The idle and irregular are put to shame by the examples of their industrious and more zealous fellow-students. The improved character of the medical education, imparted in our hospitals and colleges, has not been without its good influence, as it has left less time for idleness, and has consequently diminished the opportunities for seeking recreation in vicious amusements. But, above all, the influence of religion has been remarkably shown in exerting its hallowed power, protecting the student from those seductions to which, without its shield, he might have yielded. During my own studentship, a pious student would have been subjected to the bitter shafts of ridicule from those who were destitute of religious influences. Now, I am quite sure, he is respected by those who sit by his side in the lecture-room. During the last year of my performing my full duties at Guy's Hospital, out of four clinical reporters who were assigned to me, three were religious young men, two were teachers in ragged or Sunday-schools, one being an active member of the committee of one of the branches of the Church of England Young Men's Society.

Thus much I venture to say in defence of the character of the student of medicine; the type of which, the public, in its ignorance, is too apt to find in the caricatures drawn by the powerful pen of Dickens. There is an ample explanation of the origin of this calumny in the fact I once before had occasion to publicly allude to; that, in the days antecedent to the inauguration of the present effective system of police, when street riots were so frequent, every vagabond with a decent coat on his back endeavoured to arrogate to himself a quasi-respectability by introducing himself to the magistrate as a medical student.

In these remarks, I have confined myself to those *open vices* and *patent immoralities*, which would be visited by the rebuke of the society, into which the student would enter in his family associations. But this is at best a very low view to take of the standard of morality to which the student of medicine, who is daily called upon to mingle with the sick and dying, should attain. The appeal used by the writer of the letter "What can the Association do for Medical Pupils?" is one of the deepest interest. Although he has been led to remark that "no man careth for the student of medicine," he may feel assured that there are numbers of the members of his profession who devote many an anxious thought to their welfare.

When the ASSOCIATION is summoning its committees to consider various questions touching the *morale* of our profession, would it not be well, nay, is it not an imperative duty, to devote some time to the consideration of the grave subject alluded to in the letter of "A Medical Student"? Would not the axe be indeed laid to the root of a gigantic evil—one whence arises much of the bickerings, jealousies, and miserable heart-burnings in the practice of our profession—if something could be done towards the moral and ethical training of our students during the years of their most serious temptations; spent of necessity in the midst of the vices of our large cities and towns?

The "Medical Student" has suggested the general adoption of the collegiate system at all our medical schools; but those who know anything of the absolute inutility of the most stringent college rules in excluding vicious habits, where the heart desires to indulge in them, must be painfully aware that such a system, however desirable for other reasons, must fail utterly in producing the results anticipated by the writer.

From anxious and large experience, I am convinced that no great improvement will ever take place in the ethics of our profession, until the religious training of our pupils is made a matter of solicitude by those whose influence is respected by them, and whose example should guide them. Let me point to the great change which has occurred in the masses of young men in London, by the establishment of the Young Men's Christian Association. I happen to know much of the working and results of this society; and nothing can be more gratifying than to listen to the accounts given of its influence among young men, by those who have large numbers in their employment. This society is chiefly limited to those who are employed as apprentices and assistants in the various houses of wholesale and retail trades; but several members of our profession are among its active members. Only four days ago, I met, in consultation, a surgeon who is secretary to one of its West-end branches; and he informed me that one of its zealous members is at this moment a surgical officer of a large hospital.

I would venture to suggest that some association of a similar kind be commenced, under the auspices and patronage of the Medical and Surgical Association. I am sure there are many of its members who would emulate the zeal and energy of our

London merchants, and others, who conduct the management of the society to which I have alluded. If this were commenced by a small branch for each of our hospitals, or one branch for two or three when sufficiently near to each other, who could calculate the good influences which, by God's blessing, might result to the tone and efficiency of our profession, and the mutual happiness of its members?

Already does the nucleus of something of this kind exist in several of our hospitals. In more than one of them, several of the students meet together on one evening of the week for study of the Holy Scriptures and mutual edification. Only a week ago, some rules were placed in my hands by one of the students of Guy's, adopted at a previous meeting of a small Bible class which existed among them. The following are three of the rules which they proposed for the guidance of the society they were anxious to organise. These rules will shew the spirit that is afloat among some of the students. May it be the privilege of the ASSOCIATION to fan it into a bright light, and not to quench it by neglect!

Rule 1. That a medical Christian association be formed, composed of members of the profession and students.

Rule 3. That the object of this association be to promote spiritual religion amongst its members; and to diffuse the same among all others who come within the sphere of their influence.

Rule 4. That the means employed for these objects be the study of the Holy Scriptures, devotional meetings, addresses, and any other means which may from time to time present themselves.

I would offer an apology for the subject of this communication in a strictly professional journal, had it been any other than the ASSOCIATION MEDICAL JOURNAL. But this Association, in undertaking the great question of medical ethics, has shewn that its supporters regard the moral relations of the members of our profession to each other, and to the public, as a matter of not less vital importance than the improvement of medical science. Never will practitioners of medicine perform their mission so usefully, and with so much mutual happiness, as when permitted to adopt *in spirit* the inspired advice: "Finally, be ye of one mind, having compassion one of another; love as brethren; be pitiful, be courteous: not rendering evil for evil, or railing for railing; but contrariwise blessing."

I am, etc., GOLDING BIRD.

48, Russell Square, Nov. 16, 1853.

MR. KING'S PAPER ON THE FETAL HEAD.

LETTER FROM HENRY S. GAYE, ESQ. TO THE EDITOR.

SIR,—In the JOURNAL of the 4th Nov. there is a paper, on "the Condition of the Fetal Head, etc.," by Mr. King. As I imagine the publication of these original papers is for the purpose of spreading knowledge, and providing data on which may be founded judicious and orthodox treatment, it appears to me that it is desirable, if any ambiguity exist in the meaning of the paper, it should, if possible, be at once explained. Mr. King makes a few assertions which are startling, and advises the adoption of a mode of treatment which I cannot but think hazardous. He says, "This high degree of ossification of the cranial bones of the fœtus, I believe, more frequently renders the operation of craniotomy and destruction of the child necessary than does contraction or deformity of the pelvis." And again: "Instead of the fetal head being found fixed or resting on the brim of the pelvis, as is to be found in all illustrated representations of this operation, we should find it moveable, and the moment we touch it with a perforator it recedes, etc." The first quotation is an assumption requiring confirmation. As regards the second, I imagine few men would be inclined to craniotomize until the head of the fœtus was firm against or impacted in the brim of the pelvis. The next paragraph is odd. "I have never heard the child cry *in utero*; but I have heard one make a most frightful noise after the head has been broken down, and the brain smashed by the operation of craniotomy, while the body was still lying in the passage. Fortunately the bed clothes drowned the sound, but it produced such a very peculiar sensation on the tympanum of my ears, and the gentleman that was with me, that neither of us will ever forget it."

May I, with all due submission, ask Mr. King, What is meant by the foregoing? Does Mr. King wish to give to the profession as an original discovery, that although he does not assert that a child cannot cry *in utero*, yet, with a broken head and a smashed brain, a fœtus can give utterance to a frightful noise?

Again, does Mr. King wish to assert that the use of the

stethoscope, to ascertain the life or death of the child, is *awful practice, and trifling with a valuable life intrusted to one's care!* Must we pay no attention to the size of the pelvis, nor to the stethoscopic diagnosis, in cases of a high degree of ossification of the foetal head?

Must we plunge our fingers into the vagina, run the tips of them against "a high degree of ossification," and as quickly let the perforator take the place of the finger? I do agree with Mr. King in thinking that the labour bed is not the place, nor the time, for *practising* the ears to sounds, or *preparing* ourselves to become stethoscopists: but is that any reason why a practised and perfect ear should not be combined with a ready and educated finger? True, we have "to muster all our moral courage to make up our minds to coolly and deliberately take away the life of a human being;" therefore are we not to satisfy our minds that we are possibly not doing anything of the kind, but merely removing an inert and lifeless mass? According to Mr. King, all that is required "is a certain amount of self command and moral courage, with a thorough knowledge of the vaginal passage, the pelvic cavity, and the situation of the uterus, a nurse, a female friend, and a friend to back one."

Mr. King has performed craniotomy fifteen times; according to his own showing, it must several times have been on account of the highly ossified condition of the head of the child. The notes of such cases would be most interesting; the thickness of the calvarium, the state of the sutures, etc. The records might be valuable addenda to our obstetric knowledge, especially as at present the general opinion is, that when the head is very large, the bones are seldom much ossified. In the case Mr. King refers to, of the head having been fractured at birth, the fracture, I should have imagined, was the natural result of a child's head coming into violent contact with a hard floor.

I am, etc., HENRY S. GAYE.

Taunton, Nov. 7th, 1853.

COMPLETE ALOPECIA.

LETTER FROM JOHN BARCLAY, M.D., TO THE EDITOR.

SIR,—Another case of alopecia is described in the enclosed letter to me from a member of the Association.

"DEAR SIR,—I have just read with much pleasure your account of a singular case of alopecia at page 902 of our JOURNAL.

"A similar instance occurred to myself here some years ago, in a patient at the Salop Infirmary. The man (who, I fear, has been dead some years) was then beyond the middle period of life, had a pale exsanguine look, was evidently feeble, and had not, so far as I can recollect, a single hair anywhere. The hairs of the scalp, pubes, chest, axillæ, and even the eyebrows and eyelashes, had disappeared. I wish I had taken as full notes of the present and former habits and health of the man as you have done; but what I have remembered is much at your service if you are collecting cases. There was certainly no obvious cause for the deficiency.

"I am, etc.,

"HENRY JOHNSON, M.D.

"Shrewsbury, Oct. 15th, 1853."

The case which I published in the JOURNAL of October 14th, and those of Mr. Morris (October 21st) and Dr. Johnson, are the only ones with which I am acquainted. I am sorry that no available hint as to treatment has yet been elicited.

I am, etc., JOHN BARCLAY.

Leicester, Nov. 14th, 1853.

ADVICE GRATIS TO MEMBERS OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

LETTER FROM JOHN CHURCHILL, Esq., TO THE EDITOR.]

SIR,—I think you must agree with me, that the manner in which you introduced my name into a leading article in the last number of the ASSOCIATION JOURNAL, demands some notice from me.

The character of a publisher is public property, and it is right that his "doings," if wrong, should be subject to censure. On the same principle, his name and reputation must not be allowed to be unjustly trifled with.

I regret, Sir, that in reply to observations which the Editor of the *Medical Times and Gazette* made in his editorial character, you have introduced my name, and in a manner which leads to the formation of a very low estimate of the dignity of an editor's position; for that gentleman, you imply, would allow me to write or dictate a leading article, simply because I am publisher of the Journal. My character is not of yesterday; for more than twenty years I have been before the profession

as a medical publisher; and I hope I may be permitted honestly to add, that by my enterprise I have contributed to the advancement and improvement of its literature.

I have, as publisher of several periodicals, been happily and most agreeably associated with many gentlemen occupying influential positions in their profession, and I appeal to them thus publicly, if I ever in any one instance attempted to interfere with or influence their opinions? I may take this opportunity of adding, that I have never asked for a favourable or biased review of any book I have published: and I appeal to you, Sir, as your publisher while you were Editor of the *Monthly Journal*, to confirm the truth of this statement.

The fact is, I know nearly as little of what each current number of the *Medical Times and Gazette* will contain as you, Sir; and I can affirm, that the article in question was not mentioned to me, nor did I know of its purport until after the number was published.

I am, etc.

JOHN CHURCHILL.

Princes Street, Leicester Square, Nov. 23, 1853.

[Mr. Churchill's letter is elicited by thanks rendered to him for gratuitous advice given in the *Medical Times* (which is his property) to members of the Association. It appears that Mr. Churchill considers the editor the only party to whom thanks are due. So be it. All thanks, all praise to the editor of the *Medical Times*, for gratuitously advising the Provincial Medical and Surgical Association to stop its journal. From respect to Mr. Churchill we publish his letter; but in doing so, we must state that the topics to which he refers were not mooted in our leader. We only spoke of gratuitous advice. EDITOR.]

NEWS AND TOPICS OF THE DAY.

[Continued from page 1029.]

THE LATE JAMES AINSWORTH, Esq., F.R.C.S.L. Our obituary of last week recorded the decease of this gentleman; but he has filled a position both in society and in his profession in Manchester, which demands a passing notice here. Mr. Ainsworth was descended from an old Lancashire family, originally of the township of Ainsworth, a member of which married the only daughter of Winkley, by the heiress of Plessington, and so acquired that property in the reign of Richard II. In later times, the Ainsworths were connected by marriage with the Hopwoods, of Hopwood, and possessed property at Spotland, in the neighbourhood of Rochdale. At Plessington Hall, the arms are still visible over the arched stone entrance. The name and arms of Ainsworth are also in the glass of one of the windows at Kersal Cell (Miss Atherton's). Of this ancient family, several distinguished themselves in various walks. Henry Ainsworth (who was born at Plessington in 1560, and died in 1629), the traveller, celebrated Hebraist, and biblical commentator, author of *Annotations upon the Five Books of Moses* (1627), and many other works, was one ancestor; being the second son of Laurence Ainsworth, of Plessington, gentleman, by Dorothy, daughter of Thomas Grimshaw, of Clayton. Another, not less celebrated, was the grammarian and lexicographer, Robert Ainsworth, F.A.S., author of the well known Latin Dictionary (first edition, 1736), and other works: he was born at Woodgate, Eccles, in 1660, and died in London in 1743. Jeremiah Ainsworth, the father of the gentleman whose recent decease has called forth this brief notice, was an accomplished scholar, and well known as a mathematician. He was on very intimate terms with Sir Thomas Egerton, afterwards created Earl of Wilton. Many references have recently been made to this Mr. Ainsworth, in *Notes and Queries*, with relation to the history of the rise of science in this county; for he is regarded as the founder of a school of Lancashire mathematicians.

The late Mr. James Ainsworth was born in Manchester, on March 5th, 1783; he was consequently in his seventy-first year. He was educated at the Manchester Free Grammar School, during the rule of Mr. Lawson, as head or high master; Messrs. Durby, Pedley, and Holt, being the other masters; and, after leaving the school, Mr. Ainsworth was a private pupil of the eccentric but able teacher, the Rev. Joshua Brookes. About the year 1798, when he was only 15, Mr. Ainsworth went to the Infirmary as an apprenticed pupil; there being an express stipulation in his indentures that he should be allowed a portion of the day to go and take his lessons. This time he devoted to the study of the Latin classics—a taste for reading which he retained to the close of his life. After completing his apprenticeship, he was for some time a clerk at the Infirmary, and acted as house apothecary for nearly a year, during a period when fever was raging to a fearful extent. He took

the complaint, which nearly proved fatal to him. At this time, the eminent Charles White (whose biography has yet to be written) was one of the surgeons to the Infirmary: and amongst Mr. Ainsworth's most intimate acquaintances and friends were Dr. Ferriar and Mr. Benjamin Gibson; and later in life, Mr. Ainsworth was appointed executor and guardian of the only child of the latter—a celebrated oculist in his day. Mr. Ainsworth subsequently became a student at the University of Edinburgh, contemporaneously with Lord Brougham, with whom he was at that time on intimate terms. When he had finished his medical education, he was, from his recognised ability, invited to join the grandfather of the present Dr. Henry, in partnership. Mr. Henry is well known as the inventor of the calcined magnesia and other chemical preparations still held in high estimation. Mr. Ainsworth was a very intimate friend of the late Dr. Edward Holme and the late Mr. Robert Thorpe, surgeon: the latter commencing his professional career at a much later period than Mr. Ainsworth. In the year 1800, when only 23, Mr. Ainsworth was elected surgeon to the Infirmary. He is stated to have been the first to commence anatomical lectures in Manchester, which he begun in conjunction with the late Mr. Ransome, surgeon; and he may therefore be regarded as the originator of what has since become the Royal School of Medicine and Surgery, Pine Street. It is worthy of notice, as one of the "small beginnings", that Mr. Ainsworth converted the hay-loft over his stable into a lecture theatre. He was most indefatigable and enthusiastic in the pursuit of professional knowledge, and an exceedingly skilful manipulator. Some of his preparations, we are assured, are not to be surpassed, even at the present time. As an instance, we may mention an injected preparation of a large mastiff dog, in which all the principal arteries of the body (with the sole exception of the aorta) had been successfully secured by ligature, without destroying the animal's life, and which, it is believed, was the first instance of the internal iliac artery being successfully tied. Mr. Ainsworth was always esteemed one of the ablest operators of his day. In consequence of declining years, he resigned his office of surgeon to the Infirmary some time ago, and was then elected one of the consulting surgeons to that institution, the duties of which honourable post he continued to discharge up to the close of his life. He was one of the founders of the Natural History Society, and of the Botanical and Horticultural Society, and always took a strong and deep interest in the well being and progress of both these societies, and in the museum and the gardens which they established. He was elected a member of the Manchester Literary and Philosophical Society in January 1805, so that he had been enrolled nearly half a century, and was, with one exception, the oldest of its surviving members. In conjunction with the late Mr. Thomas Fleming and others, he was one of the revivers of an old Manchester club, which is still continued, and which in its day was famous, under the appellation of "John Shaw's", from the name of the landlord, who is said to have enforced early hours upon his guests by the cracking of a large horsewhip at a fixed time. This club, of which Mr. Edmund Buckley is now president, and which still numbers three or four surviving members, may be regarded as the only link between the social and convivial institutions of "Old Manchester" and those of the present day. Mr. Ainsworth's hospitality is well known; his charity had the best attributes—it was large and catholic, while it was most unostentatious, and indeed carefully kept from the knowledge of the world at large. Mr. Ainsworth expired at his residence, Cliff Point, Lower Broughton, on Friday, October 28th. He has left a widow and one son, Dr. Ralph Ainsworth.

CORONERS' INQUEST:—IMPROPER TREATMENT OF CHOLERA BY AN AGENT OF COFFIN, THE HERBALIST. On Tuesday, Nov. 8th, an inquiry was concluded before Mr. Baker, at the Cock and Hoop, Church Street, Mile End New Town, on view of the body of George Burt, aged 27, a City ostler, lately residing at 13, Dunk Street, Whitechapel, who died of an attack of cholera, having been treated by an agent of Coffin, the herbalist, named John Stephens, who carries on the business of a greengrocer in Ratcliffe Highway.

Mary Anne Stephenson said that she was living with the deceased, who always had a good state of health up to Friday week. He on that day came home between seven and eight o'clock in the evening, complaining of severe pains in his stomach. He had been drinking hard for a fortnight, and on that (Friday) evening he stated that he had drank off a pint of porter. She gave him twopenny-worth of ginger-brandy, after which he went to sleep for a short time. He continued in

severe pain till two o'clock in the morning, and during that time his bowels were repeatedly open. She then went for Stephens, an agent of Coffin, who attended. He gave deceased some powders, which he said he was to take every quarter of an hour. He also prescribed a mixture. He left and called again between ten and eleven o'clock on the Saturday morning. When he came, he looked at the deceased. He remarked that he could do no more for him, and went away. As he was going down the stairs, she observed deceased to be dying. She called to Stephens, who returned. When he saw that the deceased was dead, he took the mixture away.

Mr. Alexander M. Champneys, surgeon, 5, Church Street, said that he saw the body of deceased about noon on Saturday last, lying on a bed. He opened the body to ascertain the cause of death. He found the brain rather more congested than natural, and there was inflammation in the upper part of the stomach. He removed this from the body, and sent it to Dr. Letheby, at the London Hospital, for an analysis of the contents. He discovered a large quantity of rice-water fluid in the intestines.

Mr. Rich, registrar, said that Stephens wished to certify that deceased died of cholera; but as he (Mr. Rich) knew he was not qualified, he refused his certificate.

The Coroner observed, that he believed there was a power somewhere to prevent unqualified persons administering medicines.

Dr. Letheby stated that the Apothecaries' Company could interfere.

The Coroner said that some steps ought to be taken to prevent ignorant persons practising in the medical profession. Here was a man who was a greengrocer, prescribing medicines; and the day previous, he held an inquest on a child who was being treated by a female for paralysis, who was an agent of Coffin, and the wife of a journeyman baker.

Dr. Letheby, being sworn, said that he was the lecturer on chemistry at the London Hospital. He examined the stomach, and found red marks and marks of irritation upon it. A quantity of a brownish powder was adherent to the coats of the stomach, which proved to be cayenne pepper and ginger. There were also small portions of broken seeds of the lobelia inflata. He had no doubt that the irritation and inflammation were the effect of the lobelia. This was likely to produce secondary effects; namely, great prostration of the vital powers. In cholera it would, therefore, be most prejudicial, as it would have a depressing effect, and increase the prostration brought on by the disease. This tendency of lobelia is well known to the medical profession. To his knowledge, 22 cases of death have occurred in this country from lobelia; while in America, in all probability, they are much more numerous. Dr. Letheby then referred to the opinion of a late celebrated physician upon the effect of lobelia, which he stated was given in a recent posthumous work of his, wherein he observes that the frequent use of lobelia was a great cause of death. He added, that in the contents of the stomach of the deceased, upon whom an inquest was held, as referred to by the learned coroner, he had found fifteen grains of the lobelia powder.

By the Coroner:—I cannot say that in this case the lobelia was the cause of death, as the deceased may have died of cholera, independent of it. I think it probable that it would accelerate death, because it acts in the way cholera does, by prostrating the system.

Mr. Glover, reporter, having stated that he saw Stephens that day, when he remarked to him that he was then attending fifteen cases of cholera. The cases were in Dunk Street.

The Coroner, in summing up, observed that he had on two occasions sent Stephens for trial at the Central Criminal Court on charges of manslaughter, and that the judges took a view of the cases different from that entertained by his juries. He thought the proper course now would be for him to send copies of the depositions to the Secretary of State for the Home Department, and to the Board of Health, when an Act might be obtained to prevent empirics and persons not qualified from administering medicine.

Verdict—"That the deceased died a natural death, which may have been accelerated by improper medicine administered by an agent of Coffin; and the jury cannot separate without requesting the coroner to lay copies of the depositions before Her Majesty's Secretary of State for the Home Department, and the General Board of Health, in order that the most full measures might be taken to prevent the illegal practice of herbalists and others, not being legally qualified, from administering medicines."

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XLVIII.

LONDON: FRIDAY EVENING, DECEMBER 2, 1853.

NEW SERIES.

GRATUITOUS MEDICAL SERVICES.

Among the various questions of practical reform agitating the professional mind of late years, there is none that has excited greater interest than the one relating to the gratuitous and compulsory unpaid medical services rendered to the public. These services have become so various, so extensive, and so onerous, that they are now by no means incorrectly regarded as an established system. No rational person can doubt that gratuitous medical services to a limited extent, under existing social circumstances, are dictated by an inevitable necessity; but the opinion has gained ground, not only that the practice springing out of such a necessity has been systematised most injuriously, but that the greatest abuses are daily engrafted even upon that which conventional usage has tolerated; and that institutions as well as individuals are prostituting, for venal and self-interested purposes, the sacred name of CHARITY by the voluntary oversight of imposition practised upon them. The continual appeals, not only to ourselves, but to some of our cotemporaries, sufficiently indicate that such an opinion prevails very extensively; at the same time, the letters inserted in another part of this day's journal are sufficient to show that there is more than one view of the subject, and that it involves many grave considerations.

Under these circumstances, there can be no doubt that the Metropolitan Branch of the Association acted wisely in instituting a Committee for the purpose of investigating the subject. The Committee is strictly one of inquiry. It is not our intention, either by a notice of communications received, or otherwise, to anticipate a discussion which can only properly arise after a report has been furnished; but we think it right to assure Dr. BARCLAY, that he is decidedly in error in assuming that the members of the Metropolitan Branch have authorised this step as a "covert attack" upon, or a "crusade" against any class of the profession. The Committee has commenced its difficult and delicate task with the greatest circumspection and prudence. Its report both in a literal and a mental point of view is at present strictly a sheet of blank paper: it will be founded entirely upon the evidence furnished, and we can have no misgiving that the labours so cautiously commenced will be conducted with candour and completed with impartiality. Being intimately acquainted with every step which has been taken by the Committee, it is right that we should make this explanation, lest Dr. Barclay and others should entertain an erroneous impression regarding the nature of its labours.

A schedule of questions is now being issued by the Committee to each member of the Association. The object is to obtain in the first place, facts relating to the nature and the actual amount of the various kinds of gratuitous services rendered by the profession to the public, and, in the next place, facts illustrative of the advantages and disadvantages—the good and the evil—of the system, and of its component parts. The Committee require well defined facts rather than

reasonings. Vague and general statements can serve no useful purpose. The questions in the schedule are numerous; and in one or two instances nearly the same question has been put in more forms than one. This has been done advisedly, that each individual may readily find a heading under which to insert all the information he may have in his power to supply.

In reference to the mode in which this schedule should be filled up, we may just refer to an argument contained in the letter from Mr. KNAGGS. It is assumed, that the practice of medicine differs from that of other professions, since the medical man is called upon "to relieve misfortunes which no human eye can foresee or guard against", and this is an argument in favour of the principle of gratuitous advice. The legal profession, it is stated, has only to remedy abuses which may be prevented. The fallacy of the argument becomes evident, when we consider that the lawyer no more renders his services gratuitously to an individual ruined by sickness, or falling into inevitable misfortunes, than to his richest client; whereas, by a conventional system, the medical man is compelled to give his services indiscriminately to the vicious as well as the virtuous, to those who bring on sickness by their fault, as well as to those who fall into it by their misfortune. Man's miseries as regards his health are not more inevitable than those relating to his social state or pecuniary affairs; and even the divine, charged with the cure of souls (who rarely undertakes his duty gratuitously), has to do with inevitable maladies arising out of the innate evil of man's nature, quite as much as the practitioner of medicine. We make these remarks to show, that general arguments, such as that furnished by Mr. Knaggs, will not afford much aid to the Committee. At the same time, we are far from entertaining the opinion that there is nothing in the argument advanced. The subject is a very interesting one, and we hope Mr. Knaggs will furnish facts exhibiting it in every point of view.

A very general impression exists, that charities are abused by servants becoming the recipients of their bounty. Those who can supply information under this head should state the facts relating to the kind of servitude, the amount of wages received, the situation in life held by the employer, the nature of the illness, etc. It is one thing for a butler to a wealthy employer, receiving from £40 to £60 per annum of salary, to be admitted as an out-door patient to a hospital for an attack of temporary illness, and another, for a servant of all-work to a small shopkeeper, with £6 or £8 per annum wages, and out of employ, to be treated for a chronic disease in such an institution; and yet both classes of cases, and all the intermediate grades, come under the general denomination of "servants". The Committee will not obtain all the information they require by a bare statement of the proportion of servants attended at any particular institution: details must be given.

Again, we are informed, that a kind of erratic philanthropy prevails in different quarters. One doctor never accepts fees from the clergy, others take none from chemists and

druggists, nor from schoolmasters and mistresses or musicians, nor from retired military and naval officers, nor from hotel keepers, governesses, or artists. In some cases we know not whether to designate it as erratic or erotic; an expert accoucheur is said to have made his practice by declining fees from actresses. In all these cases of exemption, the principle on which it is justified, and the rules by which it is guided ought to be clearly stated.

It may be expected that the replies to the questions will enable the Committee to arrive at a statistical statement of the extent to which the certificates to Life Assurance Companies are still filled up gratuitously; and also that they will be enabled to construct a schedule of the cases in which medical men are required to give certificates for public purposes without fee or reward.

It has been said that this question of gratuitous medical services constitutes a principal part of *Medical Ethics*. No doubt, in reference to any rule of conduct to be laid down, ethical principles must be appealed to; and any code of medical ethics must embrace the Christian duty of relieving our poorer brethren without pecuniary fee or earthly reward. As such, the question will engage the attention of Mr. MICHAEL'S Committee. But, important as the subject of gratuitous services is, and extensive in its bearings, it is a mistake to regard it as a principal part of medical ethics. The latter ought to embrace the right rule of conduct, in a moral point of view, of medical men in their important relation to their own body, and to society at large; their duties to their professional brethren; to their patients—rich and poor; at the bedside, as witnesses of domestic life in its privacy, and often the depositories of its secrets; in courts of justice when called upon to bear testimony to wills, or to dying declarations, or to minister to the medical necessities of those charged with, or found guilty of crime; to the reputed or really insane; and in various other relations, in which the moral conduct of the medical man, as well as his professional practice, is liable to be called into question. All this should be compassed by the Medico-Ethical Committee. The Gratuitous Service Committee has to deal almost exclusively with a pecuniary question. It is quite true, that when rules of conduct are laid down, even as regards pecuniary points, ethical principles must be regarded; but before any rule for the practical application of such principles can be arrived at, the facts must be collected and collated; and it is for this latter purpose that the cooperation of the profession is called for at the present moment.

Our space will not admit of entering more fully, at present, into these interesting and highly important topics, and we conclude by expressing a hope that the Members of the ASSOCIATION, and of the profession generally, will give their most efficient aid to these inquiries, by furnishing to both Committees a correct statement of facts in the plainest language, in order that reports may be framed, exhibiting all the points in their true light, and such as may be rendered available in the further discussion of the still wider subject of Medical Reform.

When the Gratuitous Service Committee commenced its labours, it was not contemplated to extend its inquiry beyond the boundaries of the Metropolitan Counties Branch; but it was soon found that a limited investigation would be worse than useless; and it has consequently resolved to collect information from every available source. It will be

necessary to incur an expenditure of about £50, to enable the Committee to accomplish all that it has in view; and as no funds are at the disposal of the Committee, we take this opportunity of recommending all who desire to see the subject thoroughly investigated, to remit to Mr. CHARLES, when they return the schedules, small donations in postage stamps, or by post-office order. We would suggest the transmission of donations varying from one to twenty-one shillings and upwards. If the Committee receive more money than it requires, it is proposed to hand over the surplus as a donation to the Medical Benevolent Fund.

THE INVESTIGATION OF CHOLERA.

In a previous number (p. 1007), we suggested that the manner in which CHOLERA is communicated, of which we are in total ignorance, should be one of the subjects of close investigation in the prevailing epidemic. And we remarked that those who practise in country districts were in circumstances best adapted to trace the evidence of its transmission from individual to individual, or to disprove such a mode of communication.

We then stated that it had been assumed, but not proved, that cholera is not communicated by individuals; and there is another equally unproved assumption,—that there is such a relation between “premonitory diarrhoea” and cholera, that if the one is stopped by astringents and opium, the other will be prevented. It is asserted that the statistics of house to house visitation have settled this matter, and that it has been strictly and rigorously proved, according to the requirements of science, that the mortality of cholera has been stopped by a system of visiting which has brought all the cases of diarrhoea immediately under treatment. Those, however, who have themselves known what house to house visitation effects, and not merely the paper results, will (we feel assured), be the most suspicious of these statistics, the fallacies of which are many. House to house visitation is usually not organised until the disease has produced alarming mortality, and it is not therefore brought into operation until the natural decline of the disease; and the difficulty is in determining whether the diminution of mortality is owing to the premonitory treatment, or to the natural decline of the epidemic. On the other hand, if house to house visitation is adopted early, and the disease in the place does not prove very fatal, it is quite impossible to determine with scientific rigour whether the small mortality is owing to the mild visitation of the epidemic, or to the means used. Again, when cholera is epidemic in a town, few persons comparatively escape slight relaxation of bowels, and numbers have diarrhoea from fear only; so that judicious practitioners in the last epidemic, upon discovering this, gave mere placebos to their patients, who flocked to them in shoals during the panic. All these cases, if falling into raw hands, would swell the list of “diarrhoea” cases, and thus there would be returned an enormous proportion of diarrhoea cases to deaths.

We hold it to be injurious to the progress of sanitary science, to lay down as proved, that the great mortality of cholera may be prevented by the immediate stoppage of diarrhoea by astringents and opium. Such was the dogma propagated

in 1848-9, and it is too well known that the mortality in that epidemic greatly exceeded the mortality of 1832. It is injurious, for it tends to diminish the value of the important principle, that the mortality depends on the foul air which the victims have been breathing, the overcrowded rooms in which they have been living, the dirt on their skins, and in their dwelling houses, and the beer, spirits, and unwholesome food they have indulged in *for a long time previously* to the advent of the disease. If from these causes a man's blood is impure, or his nervous system depressed, or his abdominal viscera congested and loaded, what hope can there be, when he has been subjected to a full dose of the cholera poison, that astringents, by relieving (if they even can do so) one early symptom, will neutralise the full effects of the poison itself? It is an axiom in science, that the cause should be proportionate to the effect, and there is no better evidence of the immaturity of the mind in scientific knowledge than in its attributing effects to causes which are not at all adequate to produce them. The "globulists" and "table turners" are "glaring instances" of this defective power of appreciating scientific evidence.

We believe that house to house visitation is very important, if properly carried out by an efficient medical staff. It brings to light numerous cases of cholera, which would not have been treated at all, or not early enough, and thus gives treatment a better chance: it diminishes the mortality from diarrhoea only, which is always considerable during the prevalence of cholera; and it relieves much anxiety, pain, and suffering. But, in fully admitting its uses, we still hold to the opinion that the house to house visitation and its statistics have not yet proved that cholera is to be prevented by arresting the premonitory diarrhoea by astringents and opium: an opinion introduced by the Board of Health, and, we regret to say, inconsiderately backed by the College of Physicians. The relation of "the premonitory diarrhoea" to cholera is, in the opinion of some able physicians, not yet determined with the accuracy which science demands; and our minds should therefore be kept free from a belief that it is, and some such questions as the following should be the special objects of the investigation of each, when the opportunity occurs: Are there any number of cases of cholera without any premonitory diarrhoea? Is the "premonitory diarrhoea" in any proportion (compared with other cases of diarrhoea) to the violence of the cholera? Has it been possible to stop the "premonitory diarrhoea" in malignant cases, even when seen early? What is the best treatment of the "premonitory diarrhoea"?

We are firm believers in the value of treatment in all stages of malignant cholera, in cases where there is adequate constitutional power; but, from our experience, we believe that the treatment of severe cases, to be effectual, requires an amount of care, of attention, and of perseverance, which cannot be given in large cities and towns, where the patients are very numerous. To suppose this can be effected in house to house visitation, by students of medicine and junior practitioners, who must act on a routine system, in a disease which requires the special adaption of means to the individual case, is to hope more than can be realised.

While we recognise the improved treatment now generally adopted in cholera, and ascribe the greater number of recoveries in a great extent to that cause, combined with the treatment being generally applied for and obtained in an early stage of the disease, we must admit that our best hope

of diminishing the mortality, is in keeping our towns and habitations well drained, supplied with abundance of water, and scrupulously clean; and in a more temperate condition of the labouring classes, who now indulge, to an extent much beyond those above them, in spirit drinking, in swilling bad beer, in smoking tobacco, and in other sensual excesses.

OUR GRATUITOUS ADVISER.

LAST week our Gratuitous Adviser assigned some of the reasons why he recommended the ASSOCIATION to stop its Journal, and use the advertising sheet of the *Medical Times* as the grand organ of professional progress and reform. The Association "was powerful and respected"; but now it has become impotent and disreputable. *Hinc illæ lachrymæ*: hence the lamentations in Princes Street. As the ASSOCIATION JOURNAL "is seldom used by men of great eminence as a medium for the publication of original communications"; as it "publishes reports of societies, and other medical intelligence, long after they have appeared in our columns"; as "it is not a rival" of the *Medical Times*, the *Medical Times* says, LET IT BE SUPPRESSED as a useless publication! This suppression, we are told, would please "many influential members of the ASSOCIATION, who do not think that a weekly journal is necessary for the prosperity of the Association". Our kind gratuitous adviser is, we believe, misinformed on this little matter of fact; but if he will kindly give us twenty names out of our two thousand, who desire no weekly journal in return for their subscription, we shall be as much obliged to him as we were for his first condescension in becoming our counsellor.

Our original notice was simply an expression of gratitude to Mr. Churchill for "advice gratis"; and if our colleagues bear this in mind, they will more easily understand the subjoined article, and better appreciate the nice humour involved in the heading, which humour is in no small degree enhanced to the readers of the *Medical Times* by their being kept in ignorance of the tenor of our remarks.

"THE ATTACK ON MR. CHURCHILL BY THE 'ASSOCIATION MEDICAL JOURNAL'."

"A good story is told of one of our greatest lawyers. When a young barrister, a brief was handed to him in court with a fee, but, on opening the brief, he found it was a sheet of blank paper. A little careful examination, however, led to the detection of the following sentence, scribbled in pencil:—'We have no case. Please to abuse plaintiff's attorney'. Something similar appears to have taken place lately between the Council of the Provincial Medical and Surgical Association, or the Journal Committee, or some one who is responsible to the Association for the conduct of the Journal and its Editor, who must have received instructions something to the following effect:—'The assertion is quite true that the support of the Journal absorbs our whole receipts. It is quite true that the Council are obliged to discontinue the publication of the Transactions. It is quite true that we are obliged to apply for subscriptions to carry on the battle of Medical Reform. You cannot answer this. You have no case. Please to abuse Mr. Churchill.'"

"In the last number of the ASSOCIATION JOURNAL, we accordingly find an article which has called forth the following letter from Mr. Churchill.

[The letter which we printed at p. 1044 of last number, and which contained nothing about our article by which it was elicited.]

"We have but little to add to this. We cannot refrain, how-

ever, from expressing our astonishment at the low opinion the Editor of the ASSOCIATION JOURNAL appears to have of the editorial position. We do not hesitate to say that no high-minded, independent man would ever suspect another of degrading himself to be the organ of any publisher, and that any one who would accuse a brother Editor of allowing a proprietor to act in the manner imputed to Mr. Churchill, must have very different ideas of the duties of the editorial office from those entertained by us. Had any such imputation been insinuated in other publications, we should have passed it over without notice or contradiction; but it is gravely published by one who affixes his name to a Journal that is regarded as the organ of an Association which was powerful and respected. Now that it has sunk to the position of a Society for the production of a weekly Journal, which it is only enabled to support by soliciting for advertisements from Mr. Churchill and other medical publishers; from the proprietors of the Iodine Spa, Stringfellow's battery, the resilient bodice; for M. Bourjeaud's Cautions against his shameless imitators; for notices of the cantharidine tissue, patent trusses, elastic stockings, old port, pale sherry, malt whiskey, pale ale, and various other matters which lead to the entry 'Bad debts' in the Annual Financial Statement of the Council, it is not for us to say how much of its power and respectability have been lost: but as it still numbers among its members men of the highest character and noble reputation, many of the oldest and most influential of whom are active in their exertions to restore the body to its former high position, we say to them, that the imputation cast upon us in their Journal is absolutely without foundation.

"Before concluding, we must say that a Journal cannot be considered as passing from its legitimate province when it comments on the proceedings or position of a public association. We find that last year £200 was voted from the funds of the Association to the Reform Committee, but that this year the Committee is 'to be thrown upon the private generosity of the profession'; that the publication of a weekly Journal has increased the expenditure of the Society until it is 'greater than at any former period,' and cannot be borne unless the income be steadily increased; that the Council are obliged to express regret in announcing, that the Transactions, which have always been a striking feature in the proceedings, in all probability will not be continued, because the expenditure on the Journal is so large 'as to leave little room to hope that a surplus will be left for the publication of Transactions'; that the Society had to pay £870 from its funds for the support of the Journal for six months; that it cannot support its own Journal without the assistance of advertisements; that many influential members of the Association are very unwilling to give up the publication of the Transactions, and do not think that a 'weekly Journal, or a Journal at all, is necessary for the prosperity of the Association'; that the largest Association of our profession has departed from its original objects, and has become a sort of club, for the publication of a Journal, to which the accession of new members is attributed, and which absorbs nearly all its revenue; that this diversion of funds from their legitimate object has led to divisions in the body, and openly expressed wishes from members that their money was otherwise expended, and that those gentlemen who wished to have a Journal should pay an additional subscription for it; and, lastly, that the Editor of their own Journal has acknowledged that the Association has become 'IN OUR CHARACTER OF PUBLISHERS, A TRADING FIRM CARRYING ON AN ACCIDENTAL COMMERCIAL ENTERPRISE!!' When all this is forced upon our attention, it is impossible to pass it over without comment, and we claim the right of making our comments freely, without incurring the charge of doing so from interested motives. There might at first sight appear to be some plausibility in a charge of rivalry; but a little consideration will show, that a Journal which publishes none of the lectures or hospital reports, which are the chief features of the *Medical Times and Gazette*; which is seldom used by men of great eminence as a medium for the publication of original communications; which publishes reports of societies and other medical intelligence long after they have appeared in our columns; and which only circulates among members of the Association, cannot be considered as a rival of ours. We have never regarded it in that light; and we repeat that we have a right to criticise the conduct of the Provincial Medical and Surgical Association; that we do so upon purely public grounds, and with no interested motive whatever; that neither Mr. Churchill nor the other proprietors interfere, directly or indirectly, either with the Editor or with any of the gentlemen who assist him in the editorial department; and that, if any of our remarks should call for a reply, that reply should relate to the facts we adduce,

and the arguments we found on them, and should not consist of unfounded charges against either Mr. Churchill or the Editor of this Journal.

"We sincerely trust that this will be the last time we shall have to write on such a subject, as it is our earnest desire not to enter into disputes with other Journals, but to pursue, steadily and uninterruptedly, our attempts to lay before our readers rather what is important to them than interesting to ourselves, and to make this Journal the repertory of the advancing medical knowledge of the age."

It is evident from the last paragraph of this invaluable document, that our friend did not willingly, but under the constraining influence of love and duty, step aside to recommend an extinguisher being placed upon us. We therefore once more tender thanks to our affectionate gratuitous adviser; and, in doing so, we beg to assure him that he has thoroughly convinced us of our immense inferiority to him, as well as of the small repute of the contributors to the ASSOCIATION JOURNAL, in comparison with those illustrious men who now illuminate the pages of that Journal, which, as we can never forget, once conveyed weekly to the world the lofty ethics of a HEALY.

TO CORRESPONDENTS.

NEW MEMBERS. Gentlemen who wish to be proposed as members of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION, are requested to specify to their proposers whether they desire their membership to commence before, or at 1st January 1854. The annual subscription is due immediately on election for the year during which the election takes place, and in advance on every succeeding first of January.

MEMBERS IN ARREARS are particularly requested to read the official notice published last week at p. 1029, as Law XXIV is to be enforced with strictness.

ADDRESSES OF MEMBERS. The printing of the covers of the JOURNAL for next year is about to commence. Members who wish any alteration made in their addresses are therefore requested to make a legible communication without delay to the publisher.

LIST OF MEMBERS. It is not proposed to reprint this list at present; but we intend to give all the corrections of it which we have received, in an early number. Twenty members have joined the Association since the list was published on the 21st of October, so that the total number of members for 1853 is now 1946, of whom 486 have entered since the 1st January last.

VACCINATION. Letters again unavoidably postponed.

MILITIA SURGEONS. Letters in our next.

AN OPHTHALMIC SURGEON has not communicated his name.

AUTOBIOGRAPHIES. An opportunity is likely soon to occur such as E. R. desires. We cannot say more in this place, and therefore request our correspondent to communicate his name in confidence.

ADVERTISEMENTS TOO LATE. After our arrangements for going to press were completed, several advertisements arrived. The long advertisement of new contributors to the Medical Benevolent College will appear next week. Advertisers are particularly requested to deliver long advertisements on Tuesday. Short advertisements are in time up to six p.m. on Wednesday.

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London: or to the office of the Journal. Letters requiring immediate attention, and revised proofs ought invariably to be sent to Putney.

ORIGINAL COMMUNICATIONS.

ON THE PATHOLOGY AND DIAGNOSIS OF CEREBRAL DISEASES.

By ROBERT HUNTER SEMPLE, M.D., Member of the Court of Examiners of the Society of Apothecaries.

[Read at the Medical Society of London, Nov. 12th, 1853.]

ON a former occasion, I introduced to the notice of this society some Clinical Illustrations of Diseases of the Nervous System; and I then stated my intention, at some future period, to offer some general remarks upon the pathology, diagnosis, and treatment of this class of affections. I now proceed, as far as lies in my power, to redeem that promise, with the aid of such observations as I have subsequently been enabled to make in this very obscure department of practical medicine.

Bearing in mind the limited period allotted to papers like the present, I have no intention to present an elaborate essay upon cerebral diseases; but while grouping together my observations for the sake of clearness of description, I shall carefully avoid availing myself of the works of well-known authors, and confine my illustrations to those cases which have fallen under my own care, and my reflections to those ideas which have occurred to my own mind. In order also to obviate unnecessary prolixity, I shall lightly pass over those subjects which are well understood, and on which little or no difference of opinion exists, and attach a due degree of prominence to those points which have been but little investigated by authors, or on which the opinions of well informed practitioners are divided.

With regard to the PATHOLOGY of cerebral diseases, it must be admitted that the greatest obscurity and difficulty still exist; and it is too frequently a matter almost of impossibility to connect the symptoms observed during life with the appearances revealed after death by the scalpel. But as the term "pathology" includes both classes of phenomena, it will tend to simplify the subject if I confine my remarks, in the first place, only to the appearances observed after death, or, in other words, to the morbid anatomy of the textures.

Before proceeding to the consideration of those alterations of structure which are seen in or upon the encephalon and its membranes, it is of extreme importance to notice the morbid anatomy of the calvarium, which is undoubtedly concerned in the production of many cases of cerebral disease. Independently of those instances of external injury which induce cerebral symptoms, and of which I do not intend to treat, there are morbid changes in the bony structures, occurring spontaneously, which involve serious disturbances of the nervous system.

The following cases will, I think, prove the truth of this position:—

CASE I. A woman in the Islington Infirmary suffered continually from epileptic seizures, and was under my observation for about ten years: the fits were frequent, occurring at irregular intervals, and of a very violent character. In the intermissions between the fits, her health was tolerably good, with the exception of occasional headache; her intellectual faculties were quite unimpaired. She always derived benefit from the local abstraction of blood, and she was therefore on several occasions cupped between the shoulders. Blisters were applied, and kept open in the same situation; purgatives were administered, and a strict antiphlogistic regimen was maintained. Her diet was of the lightest character; no solid food or beer was allowed; and she derived her sustenance entirely from a very moderate allowance of milk, eggs, bread, and thin broth or beef-tea. This treatment was so far successful as to afford her considerable relief; but at length the fits became more and more frequent and severe; typhus supervened, and she died. The following appearances presented themselves at the *post mortem* examination.

The body was plump and well formed, and there was a

layer of fat beneath the skin, about three-quarters of an inch in thickness over the abdomen—a rather remarkable fact, considering the tenuity of her diet. *Head.* The scalp was natural; the skull externally presented no peculiar appearance; and no difficulty was experienced in sawing it through. On removing it, however, and examining it, it was found that there existed a remarkable want of uniformity between the two surfaces of the skull in some parts, owing to thickening of the osseous structure, particularly of the internal table, which, instead of being thin and brittle, was thick and solid. Along the line of the circular incision made by the saw, the skull was of about the average thickness. The os frontis was then sawn through, immediately in front of the coronal suture. Along the line of incision made in the usual process of removing the calvarium, the thickness of the cranium was one line and a half; but the part corresponding to the right frontal eminence was half an inch thick, and the same part on the left side was five lines in thickness. All the prominent bony processes were much increased in thickness and asperity, as the crista galli, the posterior clinoid processes, the bony ridge of the petrous portion of the temporal bone, the ridges on the internal surface of the occipital, etc. The dura mater was congested, the vessels of the arachnoid membrane were also congested, and the membrane itself was opaque and thickened; beneath the membrane there were two or three drachms of serum mixed with blood. The brain was flattened in front, the depression exactly corresponding to the thickening of the internal table of the skull. The substance of the brain was firm, and the grey portion was of an unusually dark colour: but this organ presented no other peculiar appearance. The other organs of the body were carefully examined, but no morbid appearances of importance were observed.

I consider that the epileptic attacks in this case were probably due to the thickening of the internal table of the skull, and the consequent abnormal pressure exerted upon the surface of the brain.

CASE II. In the spring of the year 1850, I attended, in conjunction with Mr. Beaman, of Covent Garden, a tradesman who had suffered severely for a long period from a pain in the front part of the head, and who had likewise experienced one or two epileptic fits. When I saw him, he had long been complaining of a fixed pain about the root of the nose, at the part where the nasal bones unite with the frontal bone. He felt his head rather confused, but his intellect was by no means impaired. When he went out to walk, he was often seized with a kind of giddiness, and this feeling increased so much upon him, that he was afraid to walk out alone. The head was not hot, the pupils were natural, the tongue was moderately clean, the pulse was regular, the bowels were open. He was a stout, healthy looking man, and told me that he had never had syphilis, nor had he suffered from any other disease before. The pain of which he complained, however, and the giddiness and confusion he felt when walking out, distressed him excessively, and made him almost tired of his life. As I could discover no disease of any of the great viscera, I could come to no other conclusion than that the cause of his suffering was probably a thickening of the internal table of the skull covering the anterior and inferior surface of the brain, and that the pressure thus produced upon that organ was the cause of the symptoms. I accordingly recommended four leeches to be applied over the root of the nose and lower part of the frontal bone; I also ordered a pill, containing two grains of calomel with four of compound rhubarb pill, to be taken every night, and four grains of iodide of potassium every four hours in peppermint water. I saw him again in a week, and found that he was slightly improved, but his chief symptoms still remained. I diminished the quantity of calomel, but continued the iodide of potassium. In another week he was still much the same, but he had no recurrence of fits. I increased the dose of iodide of potassium to five grains, and continued the small doses of calomel. In another week, his gums were tender, so that he was unable to eat, and he had con-

siderable salivation. I therefore discontinued the calomel. He was not decidedly improved. I continued the iodide of potassium, increasing the dose to six grains. He continued to use this medicine; and during the summer he went out of town, but returned in September without much improvement. I now saw him again, and found that he still complained of the same symptoms; namely, dull heavy pain at the region above indicated, and giddiness and confusion when he went out to walk. The constancy of the symptoms, their localisation, and the absence of any disease elsewhere, confirmed the diagnosis I had first given, and I determined to persevere in the use of the iodide of potassium in augmented doses. I therefore ordered it in doses of seven grains every four hours. The system became at last so thoroughly impregnated with the iodide, that on applying a little sulphuric acid and starch to the urine, it was at once turned to a deep blue colour. This plan was therefore assiduously continued, although I began to have doubts whether it would eventually succeed; and the patient, although very obedient and tractable, began to be tired of the quantity of medicine which he was obliged to take. I ought to mention that this person was in a very good business, which he was compelled to relinquish owing to his illness.

I lost sight of this case after the year 1850; but on inquiring into the particulars a few days since, I found to my great satisfaction, that the plan I had first recommended had been pursued regularly, and that the patient had gradually recovered. He is now (Oct. 1853) actively employed in business, takes no medicine, is well and hearty, and complains only occasionally of a slight recurrence of his old symptoms.

I think I am not assuming too much in believing that this was a case of partial thickening of the skull, and that the long-continued and persevering use of iodide of potassium produced absorption of the thickened part, and thus relieved the disease.

CASE III. In August 1853, I attended a man who was brought into the Islington Infirmary, and who complained of pain in the head, over the os frontis. In this case, there was decided thickening of the root of the nasal bones, and of the inferior and nasal part of the frontal bone, perceptible to the sight and palpable to the touch. I could obtain very few particulars of this man's history, as he was of the class of persons called "tramps", who wander about from place to place, obtaining their living partly by begging and partly by stealing, exposed for the greater part of their life to the vicissitudes of wet, cold, and hunger. I considered this to be a case of undoubted thickening of the bones, causing pressure on the brain, and I tried the same system as that which is recorded in the last case. I put him upon a course of iodide of potassium, four grains being given every four hours in infusion of gentian. Although this plan was perseveringly pursued, it was not attended with success, for the man gradually became insensible and lethargic, remained quite unconscious of surrounding objects and impressions, and finally died comatose, after having had a copious discharge of blood from the nostrils. On a *post mortem* examination, it was found that the nasal bones, and the lower and nasal part of the frontal bone, were much thickened; and on the surface of the brain corresponding to this region, there was an abscess of about the size of a filbert.*

While alluding to the diseases of the bony structure in connexion with cerebral symptoms, I would allude to a want of symmetry of the two sides of the cranium, which I have occasionally observed in cases of cerebral disease.

Thus, in a case of suicidal mania, terminating fatally in a very short time after most violent paroxysms, in 1851, I found that the two sides of the skull were unsymmetrical in a very marked degree, and the skull looked as if it had been subjected to pressure, which had caused its walls to be compressed unequally. As an example of this want of symmetry, it was particularly observed that the part of the skull which, according to phrenologists, is placed over the organ of destructiveness, was prominent on the left side, and depressed on the right; while the right frontal region was prominent, and the left depressed. And in a case which I examined a few weeks since (Oct. 1853), and in which the patient died suddenly, apparently from effusion of serum in the brain, I observed the same want of symmetry between the two sides of the skull. The left frontal region was depressed, the right elevated; while the temporo-occipital region was projected on the left side, and depressed on the right.

I do not lay much stress on these cases, but I think that they deserve to be recorded; and it is possible that other cases may be found in which similar deviations from symmetry may prove to be associated with disordered cerebral manifestations.

The morbid anatomy of the cerebral membranes is involved in very great obscurity, the most violent symptoms during life leaving often very few traces observable after death; and, on the other hand, appearances usually described as morbid are found unconnected with any cerebral symptoms during life. I have been in the habit of examining the brains after death in all cases whenever practicable, whether the patient had exhibited cerebral symptoms during life or not; and by a comparison of a few of these cases, it will be seen that the appearances observed are very unsatisfactory; and that, without a knowledge of the case before death, the investigator might be easily misled in endeavouring to trace by the scalpel the causes of the fatal event. It is certainly of very great importance that the morbid appearances in the cerebral membranes should be accurately and strictly defined, and that vague description should be banished altogether from this department of pathological anatomy. When we find writers professing to explain, for instance, the pathology of insanity, and telling us that, in a hundred cases, two-thirds exhibited disease of the arachnoid membrane, such disease consisting in "effusions on its surface", "effusions beneath its surface", "more or less opacity", etc., we are tempted to inquire whether these can be properly considered as morbid phenomena at all; or, at any rate, whether they might not be discovered in the heads of any hundred persons taken indiscriminately from a general hospital. The error committed by such writers is, no doubt, due to the fact that, being specialists, they examine only the heads of persons who have suffered from some one form of disease; and the *post mortem* appearances are afterwards adduced in support of their "foregone conclusions".

The best instances of diseased conditions of the cerebral membranes are those observed so frequently in children who die of the malady termed hydrocephalus. In the fatal cases of the acute form of this disease, an abundance of fluid is poured out into the ventricles and into the theca vertebralis; and besides this abnormal effusion, there are very frequently observed masses of coagulable lymph, especially about the base of the brain. Both phenomena are clearly due to inflammatory action; for the heads of children whose brains have not been diseased do not exhibit such conditions. But in adult years, although the symptoms of meningeal inflammation may be very distinct during life, we do by no means uniformly discover after death appearances which are at all in proportion to the violence of the attack. Indeed, it is very difficult to understand why an inflammation, involving only the slender web-like membranes covering the periphery of the brain, should excite such a violent commotion in the mental and physical powers, and should so frequently terminate in death, while a large tumour or an extensive abscess in the substance of the brain may exist for a long period, without materially de-

* In a discussion which took place at the Westminster Medical Society, in 1848, Dr. Cornack, in alluding to the causes of puerperal convulsions, took occasion to notice the views of Rokitsansky, who has ascribed the growth of intra-cranial osteophytes during pregnancy. Dr. Cornack then proceeded to argue that not only might such adventitious growths give rise to convulsions in the puerperal state, but their persistence might also account for epileptic seizures at subsequent periods; and farther, that in both sexes, and in non-*puerperal* states, epilepsy might be caused by bony growths pressing upon the brain. These observations are recorded in the *London Journal of Medicine* for January 1849.

ranging the system or shortening the patient's life. But such are undoubtedly the facts; and, mysterious as the explanation may be, it is certain that the delicate film on the surface of the brain is endued with more exquisite sensibility than all the rest of the encephalic structure. In cases of diseased membranes, it is very difficult to ascertain the exact membrane which is involved; and the arachnoid membrane and the pia mater are so intimately adherent together, that their respective inflammations are almost undistinguishable. It is a curious fact, that although the arachnoid is a serous membrane, like the pleura, the pericardium, and the peritoneum, it is by no means usual (except in the case of children, above alluded to) to find exudations of plastic lymph *between its opposite layers*. The appearance usually observed is an effusion beneath the arachnoid; and this circumstance seems to confirm the view of Rokitsky, who is inclined to regard the pia mater as the chief seat of disease.

The following are, I think, illustrative cases on this point:—

CASE IV. A woman, 68 years of age, is suffering from acute rheumatism in the wrists; the disease attacks first one wrist, then the other; it is treated in the usual manner. She is bled; warm fomentations are applied to the joints; calomel, colchicum, and purgatives are administered. Suddenly, the pain quits the joints, and cerebral symptoms appear; the head is hot, the pulse rapid, the mind is wandering; in the course of twenty-four hours, coma supervenes, and the patient sinks. An examination of the head is made after death, and nothing is revealed beyond the effusion of some limpid fluid in the subarachnoid space, and a vascular appearance of the arachnoid membrane, due probably to inflammation of the pia mater, seen through its transparent texture. The arachnoid membrane is not thickened, and the brain itself exhibits no morbid appearances.

CASE V. A respectable and steady man, in the middle class of life, about 35 years of age, suffers from dyspeptic symptoms, which, however, do not seem of a very severe character, and are treated in the ordinary manner. He becomes, however, gradually worse; his mind begins to be confused, and he takes to his bed; his head is hot, and his pulse is full and strong. A copious bleeding is practised with some degree of benefit, and the blood is buffed and cupped; calomel is then freely administered, but he becomes worse and worse; coma supervenes, and he dies. An examination of the head is made; but nothing is found, after the most careful investigation, but an effusion of transparent lymph beneath the arachnoid membrane.*

Now if we compare these cases, which I think are undoubted instances of cerebral meningitis, with others in which no cerebral disease appeared to exist during life, we shall often find in the latter copious effusion beneath the arachnoid, with decided thickening of that membrane.

CASE VI. A woman, aged 34, was admitted into the Islington Infirmary, labouring under hypertrophy of the heart, with disease of the mitral valves, apoplexy of the lungs, and general anasarca; but without any cerebral symptoms. She died about a week after her admission, and a *post mortem* examination was made. It was found that the morbid appearances in the chest corresponded to the symptoms during life; and the following was the account given of the condition of the cerebral organs. The scalp, skull, and dura mater, presented no peculiar appearance. The arachnoid membrane presented an inflamed appearance, owing to the minutely injected vessels of the pia mater being seen through it; it was also thickened in

a few places. A large quantity of thin serous fluid was found beneath this membrane, also in the ventricles, and in the vertebral canal.

CASE VII. A woman, aged 64, of a sickly constitution, suffered from hypertrophy of the heart and pneumonia, of which diseases she died, but without exhibiting any cerebral symptoms during life. A *post mortem* examination was made, and the diagnosis of the thoracic diseases was confirmed. The following were the appearances observed in the head. The scalp and skull presented no morbid appearance. The dura mater was congested, and the sinuses were full of half-coagulated blood. The vessels of the pia mater seen through the arachnoid were highly congested, and injected to their minutest ramifications. The arachnoid membrane was thickened at the vertex, where it presented an opaque, pearly appearance, owing to the effusion of serous fluid beneath it. The quantity of serous fluid was upwards of three ounces. There was a little fluid in the ventricles; their lining membrane was congested, and the choroid plexuses were oedematous.

I might multiply cases of this kind to an indefinite extent, as I have notes of many *post mortem* examinations, in which the same appearances have been observed. I confess that I formerly laid so much stress upon the phenomena usually described as characteristic of meningeal inflammation, that I carefully noted all cases where the arachnoid membrane was thick and opalescent, and where there was serous effusion beneath it; and I considered that these appearances were due to the existence of arachnitis during life. I am now convinced, however, that all these appearances may be observed, without the necessary pre-existence of any inflammation of the membranes at all, at least in the sense in which that term is applied. I believe that the thick and tough condition of the arachnoid membrane is a very common occurrence, especially as age advances; and that the effusion beneath its cerebral layer is often to be considered either as a *post mortem* change, or as caused by the same laxity of the extreme vessels as gives rise to passive exudations of serous fluid in the pleura, the pericardium, the peritonæum, and in the general subcutaneous areolar tissue.

Now I believe these observations to be of great importance, because there is too great a tendency in the present day to jump at conclusions, and, in the department of pathology, to consider as pathogenetic phenomena appearances which are not truly morbid at all.

If it be asked, then, what are the appearances observed after death, in cases which have died of meningeal inflammation, I reply that they are by no means necessarily well marked. If, indeed, the arachnoid *alone* be the seat of disease, then we should expect to find what we do occasionally find; namely, the results of serous inflammation, the thickening of the membrane, and the effusion of plastic lymph *between its opposed surfaces*; but this is comparatively rare; and in the more common case of subarachnoid inflammation involving the pia mater, the appearances after death may be very inconspicuous. Nor can we wonder that such is the case: for inflammation of the pia mater is *not* followed by effusion of plastic lymph, and the only appearances which we can expect to find would be increased vascularity and the effusion of limpid fluid. But, at or after death, the minute arteries are usually emptied, even although inflammation may have existed during life. Thus, if a person were to die while he was suffering under an attack of conjunctivitis, we might find the conjunctiva very slightly injected, or perhaps not at all; and, indeed, if a person faints, during an attack of conjunctivitis, the membrane is pale while the fainting continues. It is, therefore, by no means extraordinary that inflammation of the pia mater should leave very few traces after death, more especially when the course of the disease has been rapid, and the inflammation has not had time to induce disorganisation of the adjacent tissues.

It is necessary, then, to be extremely cautious in forming our judgment in cases of meningeal inflammation; and a correct result can be attained only by comparing carefully

* I have selected these two out of a number of cases, because I think there can be no doubt in any reasonable mind that they are instances of cerebral meningitis. In the first case, it is distinctly obvious that the inflammation was transferred from the fibrous surfaces of the joints to the cerebral membranes, or, in other words, was an example of what has been called *metastasis*. In the second case, again there is distinct evidence of inflammation within the head, and I think the cupping and buffing of the blood afforded very strong proof that a membranous structure was involved. In the obscurity which attended the case during life, this circumstance struck me as affording the proper clue to the diagnosis.

the symptoms observed during life, with the appearances revealed after death. I believe that the following rule is in accordance with observed facts; namely, if a patient, who is not suffering from albuminuria, have a hot head and a hot skin, vomiting, squinting, delirium; if the blood which is drawn be buffed and cupped; if the patient become comatose and he dies; and if after death there be found increased vascularity of the pia mater, and effusion beneath the arachnoid membrane, then the case is most probably one of meningitis, although the effusion be but small, and the vascularity not remarkable; but if there be an absence of all cerebral symptoms during life, then, even although there be thickening of the arachnoid and effusion beneath it, these appearances do not necessarily indicate meningeal inflammation, nor are we justified in considering them as morbid phenomena.

I pass over the pathology of inflammation of the substance of the brain, of congestion of the brain, of hæmorrhage within the brain, and of softening of the brain, because the time will not allow me to enter fully into these subjects, and because the pathology of the membranes is the subject which now most urgently demands consideration.

The DIAGNOSIS of cerebral disease is a point of very great difficulty, but of immense importance; and, although in numerous cases all treatment is unavailing, yet we are frequently enabled to effect the most beneficial results by appropriate therapeutic means. I have already shewn that formidable symptoms and rapid death, may be caused by a superficial inflammation of the brain, while a deep seated organic disease may excite perhaps no symptoms at all, and may destroy the patient only after a long duration. Again, it must be remarked that the different forms of insensibility are very nearly allied in their general appearance, and yet spring from causes wholly distinct, and require very different treatment. Four persons, for instance, are lying in a police station-house in a state of total insensibility; and yet their stupor, which is the symptom common to all, arises from opposite causes. One is a woman suffering from hysterical coma; a second is a man who is *dead drunk*; a third is poisoned by opium; a fourth is labouring under the advanced stage of inflammation of the membranes of the brain. The first is restored to consciousness by the copious affusion of cold water to the head; the second sleeps off the effects of his debauch in a few hours; the third is cured by the administration of emetics, and the use of the stomach pump; the fourth may be recovered by a large blood-letting. Yet if any of these remedies be applied to the wrong cases, the most deplorable results would ensue: a large bleeding in the hysterical case or the case of intoxication would aggravate the symptoms tenfold in the first, and change the temporary stupefaction into the sleep of death in the second case; the affusion of cold water, and the administration of emetics, would accelerate the fatal event in the case of meningitis. Although these cases are grouped together for sake of distinctness, the occurrence is not an imaginary one; and such instances, though not perhaps occurring all at once, are frequently observed in practice.

Again, two persons, rather advanced in years, drop down insensible, without any previous warning; but one is suffering from softening of the brain; the other labours under vascular congestion of the same organ. Wine, brandy, ammonia, and ether, may possibly restore the one; a copious bleeding is the proper and perhaps successful treatment for the other.

Once more; two persons are delirious and unmanageable; but one suffers from inflammation of the substance of the brain, the other from delirium tremens: the first shall derive the most marked benefit from bleeding, purgatives, calomel, and the local application of ice; the second shall be tranquillised by large doses of opium.

Nor must it be forgotten that the most terrible symptoms indicating brain disease may exist without any structural derangement of that organ at all, and may be due to disease of remote parts. Obstruction in the renal tubes may give rise to symptoms precisely resembling apoplexy; teething in children and abdominal irritation may produce the

most frightful convulsions. It is most essential to distinguish cases of *centric* from those of *eccentric* origin; and the life of the patient too often depends upon the accuracy of the diagnosis. The following is a case in point.

CASE VIII. A child, nine months old, delicate from birth, contracts the whooping-cough, and soon after becomes the subject of well marked and long continued convulsive attacks. The eyes are rolled about in all directions, and a squint is frequently observed; the thumbs are drawn in towards the palms of the hands: the child takes no notice of the objects which formerly interested it. The motions are offensive; the pulse is rapid, and occasionally intermittent. The symptoms continue; the convulsions increase in violence; the pulse sinks; and the sufferer seems to be in imminent danger of being carried off in one of the fits. The child is carefully examined: the head, although hot during the continuance of the fits, is cool in the intervals; the eyes, although irregularly rolled about, are not much affected when turned to the light, and the pupils are neither contracted nor dilated in a morbid manner, but contract on the approach of light, and expand when it is withdrawn. The tongue is not very foul, and there is no vomiting; the pulse, when examined in the intervals between the fits, is steady, but rather weak; the bowels are irritable; the gums are examined, and some points of teeth seem to be struggling through the gums. *The child is not suffering from organic disease of the brain*; leeches are not to be applied to the head, and calomel is not to be administered. The gums are freely lanced; the breast-milk, on which the child has been living, is withdrawn, and well selected artificial food is substituted; chloroform is inhaled to moderate the convulsions; rhubarb and soda are given at regular intervals; hydrargyrum cum creta is occasionally administered; and weak brandy and water is sometimes ordered when the exhaustion is urgent. No improvement is observed for some time; the fits are still very violent, especially after the ingestion of food; but, after a time, the convulsions become less frequent and more slight, and finally disappear altogether.

In a case like this, if the practitioner were to be guided only by the more prominent symptoms, namely, the convulsive actions, he might infer that cerebral inflammation existed; and a treatment based upon that view would undoubtedly accelerate, if it did not cause, the death of the patient.

CASE IX. On the 1st of September of this year, I was called to see an infant, a fortnight old, who was said to be suffering from constant convulsions, which had resisted all ordinary methods of treatment. On examining the history of the case, I found it to be the following:—The lady, who was the mother of the infant, was rather weak, nervous, and hysterical; and, during the early part of her pregnancy, she received a great mental shock from her husband betraying some well marked symptoms of aberration of mind, of which, however, he soon completely recovered. Her labour was a tedious one, but was not marked by any other peculiarity, unless it be deserving of mention that the gentleman who was to have attended her in her confinement was out of town at the period, and she was obliged to accept the services of another practitioner. She recovered rapidly from her confinement; indeed, she thought herself so well, that, contrary to the advice of her medical attendant, she was out of bed in a week. About this time, the infant began to be convulsed, which caused her very great alarm. When I first saw the case, I found the infant convulsed very frequently, but sleeping in the intervals: the eyeballs were thrown about in various directions; and the thumbs were drawn in towards the palms of the hands. I found, however, that the head was not hot; that there was no vomiting; that the tongue, so far as I could see it, was not foul. The skin generally was cool, and slightly moist; the pulse was 120, and regular; the child took the breast-milk with avidity; the motions were yellow, and without any disagreeable odour. On turning my attention to the mother, I found her in a very weak and nervous condition, and walking about the room, although only a fortnight had

elapsed since her confinement. Her pulse was very weak, her face pale, her breasts flabby, her milk thin. I therefore directed particular attention to her state. I recommended her to go back to bed; to drink milk, and occasionally bottled stout; to eat mutton chops; to take quinine; and, as far as possible, to keep her mind at rest. For the baby, I recommended only a little powder of soda and rhubarb to be given occasionally, as I felt convinced that the convulsions were *eccentric*, and not caused by any disease of the brain or spinal cord. I also recommended milk and water with sugar to be occasionally given to the infant. When I next visited the cases, I found that the mother was already better, her pulse stronger, and her mind more composed; but the infant still had convulsions. I now recommended the mother to discontinue nursing; and, as there was a person in the house who had a good breast of milk, I directed the infant to be applied to it, and saw the child drink with avidity. I made no other alteration in the treatment. Three weeks afterwards, I was again requested to visit the case; and the mother, who was much better, considered the infant's condition as hopeless, as the convulsions had continued ever since my former visits, but not quite so frequently. But, after again carefully examining the child, I assured her that it would in all probability recover, and recommended change of air both for mother and infant. I also recommended a mixture for the child, containing a little tincture of *assafoetida*, with *magnesia*, to be given at regular intervals. I did not see the case again; but I am informed by the medical gentleman who had the charge of the case, that my original view had been correct; that the convulsions gradually became less and less frequent, and less violent; that both mother and child went to Brighton; and that no farther medical attendance was considered necessary.

Now, I do not by any means assert that cases like those just recorded are free from danger, or that we are justified in giving a decidedly favourable prognosis; for in very young infants, and in children during dentition, the very violence of the functional disturbance may carry off the patient at once, or wear out the powers of life by its long continuance; but I boldly declare that a correct diagnosis will save many patients whom an incorrect one would destroy. The routine system of applying leeches, giving calomel, and administering purgatives, however useful in cerebral inflammations, is destructive to the patient in functional disorders of the brain; and, in these latter cases, the use of mild alteratives, and strict attention to diet and regimen, will often effect a cure.

As I have confined my remarks chiefly to diseases affecting the skull and the cerebral membranes, and to those disorders which may be mistaken for them, I shall conclude with a summary of the chief points of diagnostic importance.

1. When a person suffers from constant and dull pain in the head, with or without convulsions, the pain being limited to a certain region, the external surface of the head being cool and the pulse regular, the digestive system not much or not at all disturbed, and the intellect unimpaired; if any thickening of the bony structure can be perceived, or if the patient has suffered from syphilis, it may be conjectured as probable that there is thickening of the skull, and that the symptoms are due to that cause. In such a case, a moderate diet should be enjoined; leeches may be occasionally applied; the bowels should be kept gently open; but I think our chief reliance should be upon the internal administration of iodide of potassium in increasing doses, and continued for a long period.

2. When there is pain and heat of the head, vomiting, nausea, want of appetite, foul tongue, derangement of bowels, rapid and full pulse, squinting, delirium, thirst, and subsequent coma, and if the blood drawn be buffed and cupped, there can be little doubt that the case is one of meningeal inflammation.* In such a case, there is no time

to be lost; the warm bath must be used in the case of a child; cold must in all cases be applied to the head; leeches are always necessary: calomel is to be freely administered, and alterative aperients must be given at the same time. By the adoption of such measures many valuable lives may be saved.

3. When the head is cool, the pulse moderate, the tongue clean, the motions healthy, *then*, although there may be the most violent and long continued convulsions, squinting, drawing in of the thumbs towards the palms of the hands, and all other symptoms indicating deranged action of the nervous centres, there is nevertheless an absence of serious centric disease. We may here reasonably hope for a favourable termination by the use of ordinary hygienic means; such as lancing the gums, if the patient be undergoing the process of dentition; attending to the quality of the breast-milk in very young infants; correcting any ascences in the *primæ viæ*; change of air, and the judicious use of stimulants and tonics; and the adoption of all such other means as are calculated to improve the powers of the system in general.

It cannot be urged in too strong terms, that the mere existence of convulsions, however alarming they may appear, does not indicate, *alone*, a serious disease of the brain; these movements are merely the external manifestations of cerebral irritation, and are often caused by circumstances comparatively trivial. On the other hand, it must be remembered that, at all periods of life, the cerebral membranes, especially the *pia mater*, are apt to take on inflammatory action; and that, slight and web-like as this membrane is, and insignificant in appearance as are the lesions which it exhibits to the scalpel or to the microscope, yet upon its integrity or its unsoundness often depends the brightness, the perversion, or the obscurity of the intellect; and that an inflammatory disease of its texture is one of the most frequent causes of death. The most energetic treatment often fails to rescue the patient from the grave; but it is nevertheless of paramount importance to detect the malady during life, and, if possible, to arrest its progress.

8 Torrington Square, November 1853.

AN INQUIRY INTO THE RELATIVE MERITS OF THE INTRA- AND EXTRA-PERITONEAL METHODS OF HERNIOTOMY.

By JOSEPH SAMPSON GAMGEE, Esq.

WHILE working in the Florence Hospital, two years ago, I expressed surprise to my friend Dr. Palamidessi, the assistant clinical surgeon, at finding that, in operating for hernia, no attempt was ever made in that institution to reduce without opening the sac. Hence arose a discussion on the merits of this plan, which resulted in the doctor promising that he would put it to the test when a fitting case presented itself: he accordingly did so, but not without the propriety of his practice being called in question. At this juncture, he called upon me to furnish him all the evidence in my power in support of the extra-peritoneal operation. To comply with this request, I was led to devote considerable time to bibliographical research and analyses of cases. At the close of this investigation, I have been surprised at the unsatisfactory state of knowledge on the subject; the opinions of distinguished surgeons being conflicting, and facts to reconcile them not at hand. Seeing moreover that, so late as 1850, Mr. Hancock deemed the question of sufficient importance to devote to it the greater part of an exceedingly able and elaborate monograph, in which he has enunciated propositions at variance with received opinions, and, in my opinion (I emit it with much deference), not in accordance with established facts, I am induced to methodise a few of the notes which I made in the pursuit of this investigation.

Originally performed in a case of strangulated inguinal hernia in the early part of the last century, by Jean Louis Petit, and subsequently in a considerable number of cases

* I think it is hardly necessary to state that I am supposing the patient to be free from previous disease of other organs; for I purposely exclude these cases of pseudo-cerebral inflammation which may be due to fever, albuminuria, uterine diseases, etc.

by Ledran, the extra-peritoneal method of herniotomy did not gain much repute until 1788, when Monro strenuously defended it, after having put it to the test of even wider experience than had been done by Petit. Sir Astley Cooper, Boyer, and Lawrence, recommended it in particular cases. No further decided impulse was given to its generalisation until 1833, when Mr. Aston Key devoted to its advocacy a monograph so rich in facts and sound surgical arguments, that most English surgeons adopted the innovation, and soon found reason to publish their testimony in its support. Mr. Luke, in particular, has laid claim to be regarded as an advocate of the operation, by the statistical evidence which he has supplied. With a voice so unanimous have the majority pronounced themselves followers of Petit and Monro, that the merit of their operation would appear to be no longer matter of question; but though the rank of dissentients be unimportant in point of numbers, their character renders them formidable: among them are Mr. Syme and Mr. Hancock.

In the third edition of his *Principles of Surgery*, published in 1842, Mr. Syme unconditionally condemned Petit's operation; but in 1851, feeling it requisite to explain the changes which had taken place in his sentiments since the publication of his last edition, he thus alludes to the subject under consideration:—"The late Mr. Aston Key and Mr. Luke, of London, have done much to revive and establish in practice an old proposal for lessening the risk of operations for hernia, by dividing the cause of constriction without opening the extension of peritoneum which constitutes the sac. The advantage attributed to this procedure, is that which may be supposed to result from having the serous membrane entire, and in protecting it from the risk of inflammation; while the disadvantages alleged to attend it are the dangers of wounding the intestine in dividing the stricture, the evils which may arise from reducing the strangulated parts in a state unfit for their admission, and the mischief which may arise from abortive efforts to effect reduction when it is impeded by adhesion or other change of the parts contained within the sac. On the whole, I feel satisfied that, as a general rule, it is better to open the sac; and that the procedure in question should be restricted to the treatment of large hernial protrusions, such as those of the scrotum, and of patients in unhealthy hospitals, where a strong disposition to inflammation of the serous membrane may be inferred from the frequency of erysipelas and phlebitis."* So striking is the difference in Mr. Syme's opinion in 1842 and 1851, that it cannot but be matter of regret that he has not deemed it advisable to state in detail the reasons which have induced it. But, in point of fact, though he has explicitly opposed Petit's operation, even in his last publication, the terms in which he has expressed himself imply a forcible argument in its support. From his admission that in "patients in unhealthy hospitals, where a strong disposition to inflammation of the serous membrane may be inferred from the frequency of erysipelas and phlebitis", it is advisable to perform Petit's operation, it is evident that Mr. Syme believes that by not opening the sac the tendency to peritonitis is lessened. Hence arises a great reason for the preference of Petit's method whenever practicable: peritonitis being one of the great causes, if not the greatest, of mortality after operations for hernia. The advocates of Petit's operation cannot but infer an argument in support of it, from the very fact of Mr. Syme having in any degree deemed it necessary to slacken the force of his opposition to it, after the addition of nine years to his experience, which was already very great when, in 1842, he expressed himself in terms so decidedly adverse; they cannot but see some analogy in cause and probable effect, between this change in Mr. Syme's opinion, and that which took place in Mr. Liston. In 1840,† Mr. Liston stated, that in operating for femoral hernia, when the sac has been exposed, it is to be opened with great caution; and he commented on the recommendation of some, that the sac should

be left undivided, and that the stricture should be relieved by passing the knife on the outside, by observing that the stricture cannot be well relieved unless the neck of the sac is cut, along with the resisting fibres exterior to it. Six years afterwards, he thus alluded to the practice of endeavouring to reduce without opening the sac:—"I have fortunately succeeded in effecting this object in a considerable number of instances, within these few years, and it is a proceeding which I should strenuously advise the adoption of, when nothing contra-indicates it." The result which followed the trial of Petit's operation in Mr. Liston's hands, is precisely that which has attended it since it was first imagined. Opposed on the ground of preconceived opinions, it has steadily gained in repute, in proportion as it has been put to the test of experience.

Mr. Hancock's opposition is far more decided than is that of the Edinburgh Professor. "Opening the sac", he says,‡ "does not increase the danger of the operation; but, on the contrary, is to be preferred as the safer mode of proceeding." So forcibly and ably, and in many respects so plausibly, has Mr. Hancock defended his opinion, that it deserves most attentive consideration. If correct, it is calculated to do much good; otherwise, its adoption must be attended with practical mischief, of a magnitude proportionate to the immense importance of the affection, as a rule in the treatment of which it is propounded.

The array of authorities—Dupuytren, Richter, Hey, Heister, Sir Astley Cooper, Lawrence, South—whom Mr. Hancock cites, as opponents of Petit's operation, is *prima facie* so formidable as to deprive it of all claim to support; but it becomes very much less so when critically examined. Even Mr. Hancock admits that Sir Astley Cooper's opposition was only partial, for he recommended the operation in old and large incarcerated herniæ. But more, Sir Astley, in expressing his belief "that surgeons will employ it more generally when they shall have learned its advantages from experience,"§ pronounced a high encomium on Petit's innovation: for he implied a conviction that the reason why it was not much resorted to in his time was because its advantages were not known, and the ordinary operation was preferred in accordance with previously formed opinions; but so intrinsic was its merit, that it would only become more apparent on more experience, and impel surgeons to adopt the new method by practically convincing them that it was the best. Qualified are also the objections of Heister;|| but what is of even more importance is, that there is no evidence of their being the fruit of experience; they rather bear the stamp of a mere expression of opinion. "Nec mihi nec aliis præstantioribus chirurgis satis placet," is Heister's judgment on this important matter.

True it is that Dupuytren constantly practised the ordinary operation for hernia; and, in thus doing, he entered a practical protest against Petit's operation. But it is fairer to say that he overlooked it, than that he opposed it; for, after diligent search, I cannot find that he either refuted by argument the practical teaching of Petit, Ledran, and Monro, or that he sought to acquire personal knowledge of its value by putting it to the test of experience.

The accession to Mr. Hancock's cause of an authority so deservedly esteemed in practical surgery as was the late Mr. Hey, of Leeds, would indeed be considerable, if, contrary to his usual custom, this gentleman had not argued so manifestly *à priori* on the merits of Petit's operation, that no value can be attached to his objection when opposed to the experience of a large number of the most re-

‡ Op. cit., p. 2.

§ I quote the opinion of Sir Astley, from Lawrence on Hernia, p. 277 Third edition.

|| "Has igitur ob causas ut plurimum etiam in malo veteri magnoque timore præstare existimo sacculum potius aperire quam integrum relinquere: eum modum non nisi in recenti malo, ubi nulla adhuc intestinorum corruptio, nulla concretio, nullus abscessus, tuto posse adhiberi: quemadmodum et ipse Garengnotus hanc curationem tunc ad hanc observationem restringit, in altera operationum suarum chirurgicarum editione." Dris. Laurentii Heisteri Institutiones Chirurgicæ, tom. iii, p. 112. Neapoli: 1749.

* Supplement to Principles of Surgery, p. 31.

† Elements of Surgery, 1840, p. 330.

nowned surgeons of the age. The following quotation will, I think, be found ample justification for this criticism:—

"It has been proposed* by respectable authorities to divide the abdominal ring, and reduce the protruding parts, without opening the hernial sac. The reasons given by Mr. Astley Cooper and Mr. Lawrence appear to me unanswerable. But, in ordinary cases, I think the advantages proposed by it are not to be set in competition with its dangers. The operation itself, as far as I am able to judge, must be much more difficult; the epigastric artery, when the operation is properly performed, is in little danger; it was never divided in any operation (of inguinal hernia) which I have performed myself, or seen performed by others; and it is by no means certain that the danger in this operation arises from making an opening through the peritoneum. Whereas, not to insist upon the impossibility of reducing the prolapsed parts, which must sometimes arise from the contracted state of the neck of the sac, the increased bulk of the parts, or their adhesion to the sac and to each other,—the uncertainty which must almost always occur of the existence of gangrene in the intestine or omentum (in which case, reduction, without opening the sac, must be considered as certainly fatal to the patient) for outweighs, in my opinion, any advantages that can fairly be supposed to arise from practice."

Richter, another of the great surgeons mentioned by Hancock as an *able opponent* of Petit's operation, is, on the contrary, one of its *most elaborate and most weighty advocates*. So deservedly reputed is he as an authority on hernia in general, and so ably has he discussed this question, that I do not hesitate to quote from him, though at length. He states very fully,† under seven heads, the reasons usually adduced against Petit's method, and adds:—"Such are the objections commonly adduced against this operation. They are imposing, but not, however, so powerful and convincing as many authors deem them. . . . If it be objected, that incipient gangrene may be met with in cases in which, the strangulation being recent, there is little reason to expect it; and that, consequently, we are never in a state of safety in adopting this method, even though the operation be performed early, and before the symptoms have acquired much gravity, I [Richter] answer that, if the surgeon, after having decided on the operation, still makes an attempt to reduce, whether with tobacco-smoke, taxis, or other means, and proves successful (the hernia is reduced without opening the sac, and its contents may be diseased), why should there not in such a case be reason to fear from the taxis what is feared half or quarter of an hour afterwards from the operation? Will the surgeon be blameable, if he succeed in his last attempt? or will a judicious surgeon abstain for this motive? Should not the taxis, tobacco-smoke, and all the other means, be rejected, because they all effect reduction without the sac being opened, and because, from the first day of strangulation, the sac's contents may be diseased. . . . This method of operating is too lightly considered, without any of its advantages being observed. Why is the sac opened in the operation? In order to be able to treat the diseased parts properly, to destroy adhesions, and the cause of the constriction, if it be situated within the sac; but if there be no diseased adherent parts, if the cause of strangulation be outside the sac, why then open it? I see no reason for doing so. Is not opening the sac under such circumstances, to say the least, superfluous and useless? and would it not be advisable to reduce without opening the sac, merely because there is no use in doing so?"

"Petit's method has other real advantages. It renders the operation less complicated; and the more simple an operation is, the more is it safe, easy, and perfect. It prevents the intestines being wounded, for they are not exposed. Finally, the intestines are not exposed to the air;

and no one will deny this being an essential advantage. . . . I therefore think that this plan of operating should not be rejected in all cases, but that, on the contrary, it may be put into practice, under certain circumstances, with advantage."

Mr. Lawrence has very fully considered the arguments in favour of and against Petit's operation. He does not even express himself positively against the propriety of its *general adoption*, but holds it *sub judice*, suggesting some points for consideration before it can be assented to; and sagely remarks, that the question of eligibility between the ordinary course of proceeding and this modification must be determined, like all other practical matters, by experience.* No doubt, however, exists in Mr. Lawrence's mind as to the reality of the advantages attending the performance of Petit's operation in particular cases; accordingly, he teaches, that "the plan of removing the stricture without opening the sac† is particularly applicable to large and old ruptures, especially if the parts should be adherent, as they frequently are in such cases. To separate the preternatural connexions would require a tedious and difficult dissection, with long exposure, and much handling of the viscera; and the violence necessarily inflicted in executing such an attempt renders the subsequent occurrence of inflammation almost certain. In laying open the whole of a large hernial tumour, the exposure of so extensive a surface is a source of great danger to the patient, who, in such cases, is frequently advanced in years, and therefore less able to withstand extensive inflammation and suppuration. We must remember, too, that in large herniæ, which have been long irreducible, the abdomen becomes accommodated to the diminished bulk of its contents; and that either it will not yield sufficiently to receive again the parts which have been long protruded, so that we cannot replace them, or, if we should accomplish the return, it is so painfully distended that the replaced viscera are soon forced out again. Moreover, the ring is so much dilated in those cases, that hernia will certainly reappear; and consequently there can be no expectation of a radical cure from the operation. These reflections will induce us to adopt the practice of removing the stricture without opening the tumour in all such cases."

We have yet to study Mr. Hancock's arguments.

In the belief that peritonitis is one of the great causes of death after operations for hernia, Petit's operation is defended by many, because, not involving wound of the peritoneum, and thus lessening the chances of its becoming inflamed. Mr. Hancock endeavours to dispel the hope of deriving benefit from not wounding the peritoneum, by disproving the general opinion that the occurrence of peritonitis is much to be dreaded. "Comparatively few patients," he alleges,‡ "die of simple peritonitis after this operation. Out of fifty-two fatal cases instanced by Gay, the symptoms of peritonitis alone existed only in eight; and in these the symptoms were so slight as to lead to the supposition that the patients died from the shock to their systems, rather than from the peritonitis. It is an interesting fact, that the amount of mortality is not in the same ratio as the extent of peritoneum and intestine exposed. Cases recorded prove the smaller herniæ to be those which present the most urgent symptoms; and Sir A. Cooper has related that, in the largest hernia he ever saw, having opened the sac, a large quantity of intestine with omentum protruded; but, after dividing the stricture, the adhesions were so great, that he judged it advisable not to attempt their separation; and, from the size of the hernia, it was impossible to bring the integuments over the intestine, which was therefore left exposed to the air; yet nothing untoward ensued; the intestine soon began to granulate, and gradually sprout within the wound; and the patient recovered. Boyer also gives a case which occurred to Petit. Although the stricture was freely divided, and there were no adhesions, yet the gut could not be returned. Petit therefore allowed it to remain in the wound, and

‡ Op. cit., p. 5.

covered it with pledgets of linen. The greater part returned spontaneously into the abdomen, the wound healed, and the cure was accomplished."*

Mr. Gay's table is not, however, so favourable to Mr. Hancock as appears from the above quotation. Though it be true that, out of the fifty-two fatal cases, the symptoms of peritonitis alone existed only in eight, it is very essential to bear in mind that peritonitis existed with other pathological conditions in many more cases: thus, in two cases, it was associated with portions of bowel sloughed and adherent to the ring; in three, the bowels were matted together, with or without sero-purulent effusion, and the strangulated portion of gut was ruptured; in other two cases, lymph was effused, and gangrene threatened. Though in these cases the peritonitis was not the only pathological change, it was in many a primary one—in all, a very serious complication. After studying Mr. Gay's table, I can see no reason for dreading peritonitis after operation for hernia, less than I did before I became acquainted with Mr. Hancock's objection; and I am as much as ever convinced that any plan of operation which lessens the chances of peritonitis is *pro tanto* calculated to lessen the mortality of the operation. The grounds of my conviction are the recorded experiences of many of the most eminent surgeons of all countries, and my own observations. How many are the cases in which the operation is followed by symptoms of peritoneal inflammation, which necessitate the employment of antiphlogistic remedies! How evident in many cases is the ratio between the rapidity of recovery and the activity with which these remedies are employed!

When Mr. Hancock characterises as interesting the fact that the amount of mortality is not in the same ratio as the extent of peritoneum and intestine exposed, and implicitly infers therefrom (as the context proves) that the danger of the operation cannot be in proportion to the chances of peritonitis, and that the peritoneum may be cut with impunity, he loses sight of a fact at least equally interesting and important. He has compared large and small herniæ, as if their size and the extent of the peritoneum involved were the only difference between them; but this is not exactly the case. The difference in danger between large and small herniæ depends upon a cause, in itself so active as to mask the relative effect of opening a large and a small peritoneal sac. The smaller herniæ are of the femoral kind, in which, owing to the anatomy of the parts, the constriction is most valid, and most speedily productive of ill effects. In the case of inguinal herniæ, the larger ones are as a rule the least dangerous, for a similar reason. The parts through which a large quantity of omentum and intestine has been in the habit of descending are stretched and thin, and far less able to strangle tightly, than are parts little altered from their normal position and nutrition. It is perfectly intelligible that the danger should be in direct ratio to the validity of strangulation; and it is the very reverse of paradoxical, to assert that, *ceteris paribus*, a wound of the peritoneum is a cause of danger, and yet that as a rule operations for hernia are fatal in inverse ratio to the size of the sac—to the extent of peritoneum involved.

The cases of Astley Cooper and Petit, quoted by Mr. Hancock, in which large quantities of intestine were left exposed to the air without injury, are interesting as extraordinary exceptions; but it would be no more fair to argue from what happened in them, as to the rule of operations for hernia, than it would be to predicate the effects of gunshot wounds of the stomach, from what occurred in the case of Alexis St. Martin, for the description of which we have to thank Dr. Beaumont, of physiological celebrity.

"The history of strangulated hernia proves by every-day experience that cut peritoneum may be cut with impunity. I am willing to admit that if we cut or irritate healthy peritoneum, we may induce peritonitis, although even this does not always occur; but if we cut inflamed peritoneum, the inflammation does not necessarily increase, especially

when that inflammation results from some exciting cause. An incision thus becomes a relief to the patient; whereas, when made in the healthy peritoneum, we inflict a violence on the part. I believe, and I am supported in this belief by the observations of Sir Charles Bell, that we may cut diseased with greater impunity than healthy peritoneum. The abdominal sections for ovariectomy prove this; the removal of large portions of omentum proves it; the operations for paracentesis abdominis prove it; and the success which attended my case of caecal disease tends to prove it."*

The admission that if we cut or irritate healthy peritoneum we may induce peritonitis, is at least an argument why such cutting should, if possible, be avoided in operating for hernia before inflammation has set in. Granting that removing the cause of the peritonitis is in many cases an effectual cure of it, it does not follow but that, in rare cases, the incision may be a sufficient cause of aggravation to counteract the benefit which accrues from relief of the constriction. The abdominal section for ovariectomy, the removal of large portions of omentum, and the operation for paracentesis abdominis, prove that in these particular forms of disease there is very little chance of peritonitis following the use of the knife; but they in no degree tend to subvert the common sense suggestion that once the peritoneum has become the seat of inflammation, this may be perpetuated and aggravated by the operation of another mechanical cause (an incision) when the first one (constriction) has ceased to operate.

Mr. Key's admission that the inflammation after the operation for hernia spreads from the bowel, and not from the incision in the sac, is regarded by Mr. Hancock† "as a conclusive proof that the danger and inflammation result from the violence inflicted on the gut itself by the strangulation; and that opening the sac, and thereby laying bare the abdominal cavity, has literally nothing to do with the fatal termination." The conclusiveness of the proof is fairly questionable; for though it might be just to infer from Mr. Key's observations that opening the sac does not injure it or the parietal peritoneum, it is unjust to allege that opening the sac does harm to nothing, and that the violence inflicted on the gut itself by the strangulation is the sole cause of the danger and inflammation. It is in accordance with general surgical experience to hold, until facts shall have proved the reverse, that the inflammation occurring in, and spreading from the peritoneum covering the bowel, is partly at least the result of its exposure to the air and manipulation entailed by opening the sac, and therefore that it is advisable to avoid opening the sac, unless other reasons call for it. Strenuously as Mr. Hancock insists on the impunity with which the peritoneum may be cut into in cases of strangulated hernia, it is impossible to say how he would account for the immense difference in the ratio of mortality, when the strangulation can be removed by the taxis, and when the knife is called for. Allowing that the very fact of operation being needed is proof of the greater seriousness of the case than when the taxis suffices, one cannot help regarding incision into the peritoneal sac as a most dangerous step in the operation, certainly not a harmless one.

Proceeding with the reading of Mr. Hancock's paper, we find at p. 25: "My objections to Petit's operation are, that it is not applicable to all cases." He goes on to relate as unfit, cases of strangulation by omentum and by bands within the internal aperture, and cases of gangrenous intestine. As to the two first classes of objectionable cases, let me observe that the taxis would be tried in them. In some it would fail, and then probably Petit's would fail also, and no harm be done. If it succeeded in reducing, and produced disastrous after consequences, the one method would be as objectionable as the other; and yet we presume Mr. Hancock himself would try the taxis, for he could not tell the nature of the strangulation. As to the cases of gangrenous intestine, the great majority can be diagnosed by the rational signs

* On Femoral Rupture, its Anatomy, Pathology, and Surgery: with plates. By John Gay. London: 1849, p. 79.

* Hancock, op. cit., p. 6.

† Op. cit., p. 7.

prior to operation; and it is only in a very few indeed that there would be danger of returning disorganised gut.

"Again, if this mode of operation is not intended to apply to cases in which the stricture exists in the neck of the sac, its sphere of action is very limited; and so far from becoming a method of general adoption, it will be found to apply, according to Dupuytren, to merely one case in nine in inguinal, although in femoral hernia its application is more extensive."*

But the fact that the sphere of action may be limited is not an argument why the benefit derivable from it should not be availed of in that sphere, however small it may be: because we cannot have the whole good, are we to refuse a part of it?

Mr. Hancock admits, that his objections to Key's or Petit's operation apply to a certain extent to the employment of the taxis; but he adds: "There is this distinction between the taxis and the operation, that in the case of the former, should the symptoms recur or continue, we feel that we have merely employed a preliminary proceeding, and therefore can at once proceed to operation, and ascertain the cause of mischief. We have here performed only one operation, and the patient sustains the shock and dread of merely one operation; but the case is widely different where we have already operated, and the symptoms still persist. We are led to imagine that we have done all that the case admits of—that the persistent symptoms depend upon the injury sustained by the gut. We treat the patient accordingly; much valuable, and under the circumstances most invaluable, time is lost; and should we at length make up our minds that something more should be tried, we are obliged to recommend a second operation to our unfortunate patient, with the humiliating feeling, through our selecting the wrong mode of proceeding in the first instance, we have increased his sufferings, whilst we have materially diminished his chances of recovery." Thus arguing, Mr. Hancock leaves open the question, whether, in a considerable number of cases, Petit's is less dangerous than the ordinary operation for strangulated hernia, and he objects to the former because it may sometimes fail. But the fact of a comparatively slight operation not being sufficient in all cases, but possibly requiring ulterior proceedings of a more serious nature, is *per se* no reason why the patient should not have the benefit of the milder method. Very different from Mr. Hancock's were Mr. Liston's reflections in this point.† "The attempt (to perform Petit's operation) can do no harm; it causes little or no delay; and if it is not successful, the sac after all is opened, and the operation completed. If it does prove successful, the surgeon's mind is relieved of an uncommon load of anxiety."

Mr. Hancock's criticism on the statistics of the two operations furnished in Mr. Gay's work on femoral hernia has tended in some degree to lessen its apparent weight, as evidence of the superiority of Petit's over the ordinary method; for he has shewn, that in fifteen unsuccessful cases in which the sac was opened, death occurred from circumstances, the fatal nature of which would not have been avoided by leaving the sac intact; still, Mr. Hancock feels bound to acknowledge that Mr. Luke has been most successful, and that his statistics are in favour of Petit's operation. Now, Mr. Luke's statistics are undoubtedly those which claim the most respect; for their number is far more considerable than that supplied by any other surgeon; equally unparalleled is the precision with which they are given.

As yet, however, statistics are very far from being sufficiently numerous for the decision of the question. And here I feel the necessity of observing, that in the numerous discussions to which the more modern operation for hernia has given rise, many have lost sight of the really important question at issue. The point to be determined is not which of the two operations deserves absolute preference, the extra- or the intra-peritoneal; but whether the great mortality

of the operation for strangulated hernia admits of diminution by adopting one or the other method, according to the indications in particular cases. If, as a rule, it be unphilosophical and practically mischievous for a surgeon to be wedded to any particular mode of procedure in all cases requiring a given operation, it certainly is not in hernia, the varieties of which are without number, and may presumably be benefited by adapting the means of cure to the speciality of the case.

The experience of the great majority who have tried Petit's operation almost amounts—and this more from the manner in which it has been attained than from its extent, though this be vast—to demonstrative proof that by its performance in appropriate cases the fatality of strangulated hernia will be greatly lessened; and it is certainly quite sufficient not only to encourage, but to demand further investigation, in order that we may arrive at a correct knowledge of the cases in which one or the other operation is peculiarly applicable.

Palazzo Corsi, Florence, Nov. 5th, 1853.

REMARKS ON THE EMPLOYMENT OF THE WATERS OF KREUZNACH.

By E. H. SIEVEKING, M.D., F.R.C.P., Assistant Physician to St. Mary's Hospital, etc.

[Read before the Harveian Society, Nov. 17th, 1853.]

THE German looks upon his mineral springs as the fountains of health, and considers an annual trip to Carlsbad, Marienbad, Wiesbaden, or one of the numberless watering-places of fatherland, of as great and essential importance to the enjoyment or preservation of life, as John Bull regards his three weeks' autumnal visit to Margate, Brighton, or Ryde. It is one of the many traits that preserve the general resemblance of the two great branches of the Anglo-Saxon tree on this side of the Atlantic; and it is evident from the description of Saratoga and other watering-places, by N. P. Willis and kindred spirits, that the cousinhood of North America are fully alive to the value of these temporary migrations. They do not belie their relationship even in this particular. We do not see that the French, or the Italians, or the Spaniards, quit their homes annually, as a matter of course, to obtain a renewal of health. They are more *gleba adscripti*, and are satisfied with that share of mental and bodily vigour which their permanent place of residence can afford. We need not grudge them this passive contentment. We claim as our birthright the desire for improvement, the onward-striving which pursues higher and better objects, whether in moral, in sanitary, or in political relations; and we think it a privilege legitimately to follow out everywhere the great laws of nature, by which we are told to advance not only as logs on the tide of civilisation, but as bold and manly swimmers, cleaving the waves by the might of a good arm upheld by a living faith. We seek health as one of the great boons of Providence; we seek it, not in frivolous excitement, but in that intercourse with nature and her most lovely or her grandest works, which, above all other restoratives, gives balm and solace to the sufferer.

Geographical position and opportunity have in this, as in many other points, determined the selections which the German and the English each make. Their mode of living and their character undoubtedly render a different regimen necessary in disease; and hence it is not to be wondered at that they each show a preference for a peculiar kind of medication. The vicinity of the bracing atmosphere and water offered by the sea-coast in every part of England, our love for maritime scenery, for shipping and aquatic sports, tempt the Englishman more, and seem more congenial to his beef-eating constitution, than the sulphureous springs of Harrowgate, and the antirheumatic thermæ of Bath. He inclines to regard the latter agencies on a par with the *bouillon* of French cookery, or the *ptisane* of the Gallican

* Op. cit., p. 41.

† Practical Surgery, p. 553.

pharmacien, good in their way, but decidedly unsuited to his cayennised palate. The German, on the other hand, knows nothing of the sea or of shipping; he cannot appreciate the majesty of a storm; nor, all musical though his taste, does he discern the music in its roar. He prefers the mountain forest, with its rivulet and cascade; the broad lime-tree walks, and the wood resounding with the note of the nightingale; he likes his beef boiled to strings, and he prefers his physic well diluted with water, in the shape of a mineral *brunnen*, which he drinks by the quart, under the close superintendence of His Royal and Imperial, Royal, Ducal, or Countly Upper Medical Bath-Counsellorship, the portly Physician and Comptroller-General of Blank-Blank.

The good effects and decidedly medicinal character of many of the mineral springs of Germany are undeniable. Much may be ascribed, and is justly due, in the curative influence they exert, to the change of scene, and absence of the cares of work-day life; but many of the waters are exported; and the volcanic cuisine in which they have been prepared, mysterious as it may be, enables them to produce palpable effects under circumstances which forbid those effects from being ascribed to anything but the dose exhibited. The chemist cannot account for these facts; for doses of the constituents obtained from the druggist, that would produce no results, when exhibited in the combination offered by nature's cookery, often are followed by very marked and indisputable effects. To take a single instance; Pullna water, a favourite and mild purgative, contains as its main constituent sulphate of soda. The dose sufficient to produce a decided effect with an adult is a couple of ounces; these contain altogether but about ten grains of sulphate of soda and magnesia, besides minute quantities of other salts. It follows, that the mode of combination is a point of great importance to determine the efficacy of a remedial agent; and it may serve as a therapeutic hint, that the prevailing desire to simplify our remedies, and to reduce our prescriptions to a single drug, is one not based upon the example shown us by nature herself. Moreover, it may teach us respect for the wisdom of our ancestors, who, in many respects, understood the art of compounding medicines much better than we do, though they may have been ignorant of the atomic theory, and the laws of chemical combinations.

Since the introduction of steam vessels, and the publication of Sir Francis Head's amusing volume on the *Brunnens of Nassau*, Englishmen are as familiar with most of the watering-places that lie in the route from London to Frankfort, as the Germans themselves. Fortunately, however, for the latter, the London season detains its victims until long after the great majority of invalids have gone through their prescribed course; so that they are not interrupted by the sons of Albion. We therefore rarely see the waters in full operation, or enter into the reality of a German watering-place, with all its minutiae of drinking and abluion, of diet and regimen; with its gipsy parties and musical reunions, its welcomes and leave-takings. Our acquaintance is consequently but of a superficial character, and is likely to continue so, unless the medical profession of this country make balneology a subject of study, and thus allow it that scientific importance which it legitimately demands.

Recently, attention has been directed to a watering-place which belongs to the range of the Rhine excursionists, and which promises to become a place of much resort with our countrymen, on account of the powerful efficacy of its waters—the Springs of Kreuznach.

Kreuznach is a small town in Rhenish Prussia, situated in the valley of the Nahe, a tributary of the Rhine, which receives it at the well known site of Bingen and Bishop Hatto's far famed Tower. A drive of an hour and a half along vineyards and cornfields, skirting the adjacent hills and the river, conveys the traveller from Bingen to the springs. These are of very ancient repute, on account of their yielding a large produce of chloride of sodium, which is obtained from them by the ordinary process of evaporation; this leaves behind it a residue known as *bittern* or *mother ley*.

Both the water in its native state and the residuary matter are employed for medicinal purposes; but it is only the former which is used both for external and internal administration; the latter is almost exclusively employed, diluted, as an external remedy. There are several springs, which vary somewhat in composition and temperature; they all possess a temperature peculiar to themselves, and demonstrating the volcanic character of the soil; and all contain chloride of sodium as the main constituent, with other chlorides and compounds of iodine and bromine.*

The spring known as the Elisabeth Quelle is the most in request for medicinal purposes, as the most powerful. Its temperature is 55° Fahr. throughout the year; the fresh drawn water is perfectly clear and transparent, with a slightly yellowish tinge, and of a salt, bitterish taste; a few bubbles of carbonic acid gas are visible; the water soon becomes dull; numerous small brownish flocculi form and are precipitated, and do not disappear for several days, until the precipitate is completed. The analysis of this water by Bauer, as given in Professor Osann's great balneological work, shows sixteen ounces of the water to contain above ninety grains of mineral constituents, distributed in the following manner:—

Chloride of sodium	-	-	72.922
Chloride of potassium	-	-	0.971
Chloride of lithium	-	-	0.075
Chloride of calcium	-	-	13.276
Chloride of magnesium	-	-	0.351
Bromide of sodium	-	-	0.307
Iodide of sodium	-	-	0.003
Carbonate of magnesia	-	-	1.351
Carbonate of strontia	-	-	0.683
Carbonate of baryta	-	-	0.299
Carbonate of iron	-	-	0.199
Carbonate of manganese	-	-	0.009
Alumina	-	-	0.021
Silica	-	-	0.313

90.686

The specific gravity of the water is 1.004.

The process by which the chloride of sodium is extracted from the water necessarily alters the relation of the constituents found in the *bittern*; while it removes almost all the chloride of sodium, it leaves those elements to which the peculiar effects of the Kreuznach waters are particularly ascribed in a much more concentrated form. This *bittern* or *mother ley* is the semifluid residue found in the evaporating pans; it presents a brownish yellow colour; it is translucent and clear, and has a soft soapy feel; its sp. grav. is 1.307 to 1.314. It smells like marine algæ, and has an intensely pungent and acrid taste, which is not effaced from the lips and tongue for some time after it has been applied. It is very deliquescent—a property which renders its transportation in anything but china or glass vessels impossible, as it gradually oozes and makes its way through all porous materials, and through the strongest casks and earthenware jars. It is rarely employed in the concentrated form, but mainly as an adjunct in ordinary water baths, or with the water of other mineral springs. Of late, the *bittern* has been still further evaporated to dryness, in which state it forms an amorphous light brown mass, of which I present a specimen to the society. Its taste and properties are the same as those of the *mother ley*, but it offers the advantage of being much more portable. The following is an analysis of the *mother ley* by Osann. He found sixteen ounces to contain 2625.72 grains, or about one-third of solid matter, distributed in the following manner:—

Chloride of calcium	-	-	1577.71
Bromide of calcium	-	-	388.72
Bromide of potassium	-	-	92.82
Chloride of magnesium	-	-	38.44
Bromide of sodium	-	-	154.10
Chloride of sodium	-	-	60.34
Chloride of potassium	-	-	17.30

* To those interested in the topographical and medical history of the German watering-places, we can recommend the *Lectures on the Mineral Waters of Kreuznach*, by Dr. Sutor, and published by Parker in 1851, as containing a large amount of information.

Alumina and suboxide of iron - -	35.66
Crenic and apocrenic acid, and two peculiar resinous matters, with traces of iodine - - -	216.16
Water of crystallisation and loss -	44.50
	2625.72

The quantitative analysis of the mother ley varies in almost every examination that is made, owing to the accidental variations of condensation, and fortuitous changes produced by the process of extracting the common salt; but all agree in showing the presence of a large proportion of bromide of calcium. An analysis given by Dr. Prieger, in a work entitled *The Mineral Waters of Kreuznach*, published by Mr. Churchill in 1846, exhibits a considerable difference in the relation of the constituents; it is as follows:—

Bromide of calcium - -	24.12
Chloride of calcium - -	9.20
Bromide of magnesium - -	0.48
Iodide of magnesium - -	0.18
Chloride of potassium - -	0.80
Chloride of sodium - -	1.28
Water and loss - -	63.85
Total - - -	100.00

Mr. Blyth, the dispenser of St. Mary's Hospital, has had the kindness to make a qualitative analysis of the bittern exhibited, and confirms the fact of its containing bromine. He has also found chlorides of calcium, sodium, and magnesium, but no potassium, and a trace of iron. His tests do not demonstrate the presence in this specimen of any iodine; but we have shown that the absence from our specimen of bittern does not necessarily prove the absence of iodine from the water, or from other bittern. I exhibit, by Mr. Blyth's aid, the test for bromine and iodine made by Mr. Henry's beautiful process, in the following manner:—100 grains of the bittern are dissolved in distilled water, and precipitated with a slight excess of acid nitrate of silver; the precipitate is then well washed, and carefully collected; it is then mixed with metallic zinc and sulphuric acid—both pure—taking care to have a good excess of zinc. When the effervescence has ceased, the salt of silver is decomposed, and the filtered liquor will contain sulphate, chloride, iodide, and bromide of zinc, if these elements be present. It is then evaporated to a small volume, and introduced into a narrow bottle; a cold solution of starch and some ether is added, and then some freshly prepared chlorine water is dropped in carefully; the whole is shaken together, and allowed to stand; if iodine is present, it will be precipitated as iodide of starch, while the bromine will be taken up by the ether, and will float at the top. In the bottle before you, you observe the brown ethereal solution at the upper part, indicating the presence of bromine; while the starch at the bottom retains its translucent whiteness, no iodine being present.

After the foregoing statement of the chemical nature of the Kreuznach waters, and of the residuary bittern, we shall be prepared to examine the medicinal effects; and it will be justly inferred that its action is allied to that of sea-water. Kreuznach has indeed the reputation in Germany of being *kur- & xph* the antiscrofulous spring. It is a powerful tonic and stimulant of the lymphatic system, and is peculiarly beneficial in torpid states of the constitution, and diseases based upon such a foundation. Scrofula, in all its forms of early or adult life, with the secondary maladies that spring from that prolific source, finds an antagonist of undoubted power in the Kreuznach waters. The chlorides and iodides are the very remedies which, in other combinations, we are in the daily habit of prescribing. We here find an additional antiscrofulous agent, the bromide of sodium and potassium, which manifestly increases the therapeutic effect of the other constituents. Accordingly, the nosological list—the bill of fare of the Kreuznach physician—which is found most readily to yield to the administration of Kreuznach water or bittern, comprises scrofula and tuberculosis in every variety, manifest or latent, as swellings of the external glands; diseases of the eyelids

and eyes, or the external meatus; scrofulous and atonic affections of the mucous membranes of the respiratory, alimentary, or urogenital tracts; hence also leucorrhœa, and various forms of uterine affections connected with malnutrition, are diseases well adapted for the application of this remedy, generally or locally. Chronic swellings of the bones, caries, tumor albus, are not only benefited by the waters, but yield more rapidly than to the ordinary mode of treatment. The Kreuznach waters have been also found very beneficial in scrofulous cutaneous eruptions, and in atonic states of the kidneys and bladder. The list of diseases is long; but it is rendered so rather by the refinement of science, than by that natural pathology which teaches us that there is essentially but little difference between these affections, beyond the accidental localisation of the same depraved tendency. Hence let no one say that we laud these mineral waters as a specific or a panacea: they are antiscrofulous remedies with which we are familiar, but in a guise under which they have not been hitherto known to us. We may, however, not unreasonably extend the application of the Kreuznach waters to numerous affections not necessarily allied to the scrofulous constitution; the influence of warmth applied to the entire surface in the shape of a medicated warm bath, of warm vapour inhaled in breathing, of enemata, or of the vaginal douche, is curative or restorative in a variety of ailments, especially when combined, as it will be at a place devoted to the search of health, with appropriate regimen and diet.

The value of iodine compounds given internally, or applied to the surface; the remedial power of warm baths, especially when containing chloride of sodium, has been demonstrated in numerous diseases characterised by, or inducing, degenerations of the tissues. We all know their efficacy in chronic rheumatism and its sequelæ, in secondary syphilitic affections, in atonic gout, and lead or mercurial poisoning. Their action is manifestly by stimulating the capillary circulation of the cutaneous surface, or of the kidneys; or, as Mr. Melsens has shewn in reference to lead poisoning, by a direct eliminative effect upon the noxious element. The morbid states alluded to, and their multiform complications, therefore come legitimately under the influence of the Kreuznach waters; and the progressive reputation they have enjoyed since Professor Liebig first shewed them to contain bromine, is fully borne out by the experience of ordinary therapeutics. It is not my object at present to enter into minute detail with regard to the medicinal powers of the waters in the protean forms of disease alluded to, but I may be allowed to direct attention to the remedial efficacy of the Kreuznach waters, in a species of malady in which hitherto the ordinary drugs at our disposal have failed to achieve a cure: it is the more a pleasant duty, as in recommending the Kreuznach waters for this special purpose, we do so on good evidence, based upon *a priori* grounds, which our knowledge of their chemical constitution affords, and upon the results of the practical experience of an eminent physician, Dr. Prieger, jun.* Moreover, the maladies to which we allude extensively affect those orders of society which would possess the means of visiting a foreign watering place; and, while conferring a boon on such sufferers of the higher classes, we may hope to induce some of our colleagues to employ remedies similar in constitution to the Kreuznach bittern, and thus to determine whether or not, by following the example shewn us by nature, we may spread the advantages that must otherwise accrue to but a very limited number among a more extended sphere. I may remark parenthetically, that the concentrated bittern itself has recently been imported by the German chemists Hilgenberg and Schacht of Houndsditch. They find it most convenient to keep it in solution; but it is probable that by means of a suitable arrangement, and by the employment of well stoppered glass bottles, the dry salts might become more generally accessible, as the bulk of the solution renders its transport difficult and

* Ueber Hypertrophie und die harten Geschwülste des Uterus und seiner Anhangs, so wie den Einfluss des Kreuznacher Wassers auf dieselben. Von Dr. Oscar Prieger: 1863.

costly. I am also informed that Messrs. Taylor of Vere Street have taken steps to procure a supply of the bittern.

To return: the affections to which I have alluded as not having hitherto been amenable to treatment, are fibroid tumours of the uterus and ovaries, and other hypertrophic conditions of those organs. It appears from the cases recorded by Dr. Prieger, jun., in an interesting pamphlet recently published, that under the use of the Kreuznach waters they may be softened, reduced, and even entirely dispersed. There is nothing in the structure of the tumours which renders such a result improbable. Until they have become very large, they are freely traversed by blood-vessels, the agents of all advancing or retrograde metamorphoses; and as long as the organic connexion between the morbid growth and its matrix is freely kept up, we may reasonably hope that our dynamical remedies may exert an eliminating effect, provided we can hit upon an agent likely to stimulate the system in a manner proportionate to the existing disease. Any one who will take the trouble to go to the museum of St. George's Hospital, and examine some injected specimens of uterine fibroid tumours, will find that they may be plentifully supplied with blood-vessels. The more extensive their growth, the more they seem to be placed beyond the pale of the organisation; and they gradually become, like foreign bodies, a source of mechanical irritation, or passive obstacles to the organic functions: they then necessarily cease altogether to react upon internal remedies. But I hold that the structure of these fibroid tumours is a further explanation of the comparative facility with which they yield to the resolvent action of the Kreuznach waters. They are, as I have attempted to show elsewhere, essentially an hypertrophic condition of the true uterine tissue, differing from it by that metabolic power which gives a morbid impulse, but identical with it in those points which the microscope and chemical reagents reveal. I the more confidently put forward this view, as I find it corroborated by a recent writer in the Reports of the Pathological Society for 1852-3. Dr. Bristowe there demonstrates in a most satisfactory manner, that the so-called fibrous tumour is absolutely identical in point of structure with the walls of the uterus, whether examined in the unimpregnated or impregnated condition.

The evidence which Dr. Prieger, jun., brings forward in proof of these tumours being amenable to treatment by the Kreuznach waters, is of a character to demand our serious attention. Those who will study his paper, will be constrained to conclude that he thoroughly understands his subject, and that he is not led away by that species of enthusiasm which frequently prompts the administrators of favourite remedies to regard them as agents of a universal efficacy. His diagnosis is cautious and well founded; and he gives us accurate statistical details of his experience.

The results of the application of the Kreuznach waters in eighty-six cases of hypertrophic states and fibroid tumours of the uterus and its appendages, which have been under his care, are as follows:

Thirty-one were entirely cured; of these, two were hypertrophy of the entire uterus; sixteen, partial hypertrophies of the uterus; six, fibroid tumours of the uterus; and seven, tumours of the ovaries. In each case, no trace of the disease remained at the conclusion of the treatment.

Twenty-nine were partial recoveries; the troublesome symptoms having been removed or ameliorated, and the swelling or tumour having been much reduced. Of these, three were hypertrophy of the entire uterus; four, partial hypertrophy of that organ; nine, fibroid tumours of the uterus; five, fibroid tumours of the ligaments; six, ovarian tumours; and two, ovarian tumours complicated with hypertrophy of the uterus.

Nineteen cases were benefited so far that the continued growth of the morbid formations was arrested, without any or but a trifling reduction in size. Of these, two were hypertrophic states of the uterus; eight, fibroid tumours of the uterus; four, fibroid growths of the uterus; and five, ovarian tumours.

Seven cases presented no change whatever either in the size of the tumours, or in regard to the morbid symptoms.

The method pursued and the duration of treatment by the Kreuznach waters necessarily varies according to the duration and extent of the disease, and according to the constitution of the individual. One remarkable and well authenticated fact regarding its influence upon the organism, is the continuance of the peculiar action it has set up, long after that action has been initiated, and the remedy has been discontinued. Dr. Prieger has repeatedly observed that after the conclusion of the course in August or September, the progressive diminution of the local affection continues until the following spring. Thus in a lady who had employed the baths for eight weeks, on account of an ovarian tumour, previous to the 1st September 1851, Dr. Prieger was unable to perceive a notable diminution of the tumour when she quitted Kreuznach, nor could her own medical attendant in the following January detect a marked change; still, a few months later, the tumour was found to be much reduced, and she had made use of no remedies in the interval but an occasional local application of the Kreuznach water.

We have alluded to the different modes in which the Kreuznach waters are exhibited. A few more detailed remarks on the subject may be acceptable. When administered by the mouth, the water may be taken by itself, or combined with milk, whey, or other mineral waters, and either warm or cold; the quantity varies from one to six beakers, or from a few ounces to two and more pints; it is taken in the morning at short intervals, and moderate exercise is enjoined during the potations. The baths are commonly employed tepid at a temperature of about 90° F.; at the commencement of the course the patient is ordered the use of the water only, while its power is subsequently and progressively increased by the addition of more or less of the bittern. Dr. Prieger* informs us that it is usual to commence with one quart, or about 4 lbs. of the latter for baths for adults, while a less quantity, proportioned to the age of the individual, is used for children. If the inspissated bittern be employed, we should use from one to two pounds for the bath of an adult. The increase in the quantity of bittern in the baths must be gradual; and in the same way, after the climax has been reached, it is progressively diminished; "for the whole object," to use Dr. Prieger's words, "of this management would be destroyed by a too quick reduction of the effective power, and before the accustomed irritation of the skin" (a species of critical eruption) "had subsided." The bath is rarely used more than once a day, or for more than from five to twenty minutes at a time; its action is accelerated by friction of the affected parts, or of the whole body. Rest is enjoined after the use of the bath in very delicate individuals, while gentle exercise is recommended to those of a corpulent or more robust habit. The topical applications vary equally in strength and duration according to the constitution of the individual patient; and when applied as gargles, as enemata, or as vaginal injections, we must necessarily use some judgment in regulating the minutiae of temperature, concentration, and frequency of exhibition.

My own personal experience of the advantages derivable from the waters of Kreuznach has hitherto been so limited, that I should not have brought the subject under notice, if I had not been provided with more extensive evidence than my practice has supplied. So far, however, as it goes, it confirms the statements of the authors quoted. In our case of a gentleman in whom an atonic condition of the genito-urinary system, accompanied by azoturia, had been brought on by indiscriminate medication for gonorrhoea, and where steel, quinine, and similar remedies, had failed to produce a cure, a course of the Kreuznach waters, followed at my suggestion, effectually removed all morbid symptoms. In another instance, a young lady, whom I saw in consultation with Mr. Toulmin of Clapton, and who had been suffering from a long standing chronic tumefaction of

* The Mineral Waters of Kreuznach, etc., p. 21. By Dr. Prieger.

the condyles of the femur, was restored to perfect health by a six weeks' visit to Kreuznach, and a careful attention to the rules laid down by Dr. Prieger, junior. I have recently had occasion to recommend the use of the Kreuznach bitter in the case of a young lady in whom the ordinary exhibition of iodides externally and internally failed to remove a very sluggish glandular tumour of the neck. Its brief employment, however, and the subsequent removal to the sea side, does not enable me to quote the case as one of cure. I mention these cases rather with a view to proving that my remarks proceed from a conviction of the extreme value of the Kreuznach waters and the bitter, than for the purpose of strengthening the arguments of men of larger experience. It appears that the bitter has been employed somewhat extensively at an infirmary for scrofulous children, erected by Mr. Sidney Herbert in Wilton, Hants. If so, it would be desirable that the results of its effects should be made known to the profession, as we might thus be enabled to form a more conclusive estimate of its remedial powers apart from the effect produced by the change of scene and air when patients visit Kreuznach itself. If members of the Harveian Society should have acquired any experience on the employment of this remedial agent, I should be happy to find that these cursory observations succeed in eliciting their views on a subject which I have ventured to introduce to their notice perhaps with less completeness than it demands, but with an earnest conviction of its importance in a scientific and directly practical point of view.

3, Bentinck Street, Manchester Square, Nov. 18th, 1853.

ON THE VALUE OF NITROUS ACID IN THE TREATMENT OF CHOLERA AND CHOLERAIC DIARRHOEA.

By R. H. WHITEMAN, Esq.

Now that cholera has again invaded us, and members of the profession are everywhere considering the best tactics to be adopted to successfully grapple with the disease, it is impossible to value too highly any therapeutic measure that can be proved in the least degree serviceable in arresting the more formidable symptoms. In the valuable and interesting paper by Dr. Cormack, lately read before the Medical Society of London, and subsequently published in the *ASSOCIATION JOURNAL*, there occurs the following remark:—"Mr. Whiteman, of Putney, informs me he finds nitrous acid so prompt and so satisfactory a remedy in epidemic diarrhoea, that he trusts to it in preference to any other medicine." The following observations are intended to convey a somewhat more detailed account of my experience of a medicine, which I have now exhibited with the greatest possible success to many hundreds of persons, suffering under all stages of the choleric disease.

The way in which I became possessed of my knowledge of the remedy in question, is soon told. Upwards of twenty years ago, at the outbreak of cholera in 1832, my opinion was asked concerning the probable efficacy of an original prescription, which bore the signature of Mr. Thomas Hope, at that period a medical officer on board His Majesty's Ship *Canada*. I was then in my novitiate, and thinking the chief ingredient in the formula a somewhat extraordinary remedy for a disease which I had been taught to regard as one frequently produced by an excess of acid in the *primæ viæ*, I at once pronounced against it; but was, from the strong representations of its value, and notwithstanding my prejudice, induced to copy the prescription. Shortly after, a very severe and stubborn case of diarrhoea happening to fall under my care, I determined to give the remedy I had noted a trial. The result of its administration to my sinking patient was strikingly favourable—so favourable indeed as to induce me ever after to rely upon it for the arrest of the earlier symptoms of the epidemic, to the exclusion of almost every other medicine.

I may here observe, that both the formula of Mr. Hope,

and the directions with which it was accompanied, are identically the same as those at present used by myself, and of which I shall have occasion to speak more in detail in the course of this paper.

My own experience of nitrous acid, which, as I have shown, is by no means a remedy of yesterday, fully bears out the character given it by its originator; viz., that when exhibited before the stage of collapse has completely set in, it has seldom or ever failed to check the progress of the disease; and that even when collapse has existed for some time, reaction has been established through its agency in a large number of cases, in which it has been administered along with the external application of warmth, and other auxiliaries.

In the summer and autumn of 1849, apart from the cases which occurred in my private practice, I returned to the Board of Guardians, as medical officer of the district, as many as 544 patients who had suffered more or less from the then prevailing epidemic. My belief is, that none of the cases so returned were other than fully developed cholera—cholera in its incipient stage, or diarrhoea of a decided choleraic character; for I quite agree with Dr. Cormack in thinking that, during the height of the epidemic, the choleraic type is impressed upon most diseases, certainly upon all those in which diarrhoea is more or less an urgent symptom.

In quite 350 cases of the 544 returned in the Union books, nitrous acid was prescribed. A great many slight cases amongst the poor and others were administered to at the temporary Dispensary, of which no account was kept; but out of this large number of persons, I had the singular good fortune to lose but *eleven*, or about one in fifty of those attacked.

Had it not been for the assistant, granted me by the Board of Guardians, coming to me with a most decided predilection for the calomel treatment, I believe that many more patients than I have named above would have been placed under the influence of my cherished remedy. Desiring, however, an opportunity of judging of the comparative merits of the several popular modes of treatment that were then being employed, I made no objection to a few cases being fairly submitted to the medicine so warmly advocated by Dr. Ayre; but I cannot say that the general result was at all satisfactory to my mind. The prolonged convalescence of the very few who, in my hands, rallied under, or rather got better *after* the calomel treatment, certainly afforded no encouragement for its adoption in preference to the stimulating, saline, or any other of the many plans then in use.

In the present state of our knowledge of the disease, I have ever held it to be of the first importance to commence the treatment, if possible, before the premonitory stage has given place to the more fatal and dangerous symptoms. If, then, there belonged to nitrous acid but the one property of arresting in the most prompt manner the discharge from the bowels in that stage, I should not be easily persuaded to abandon the remedy for any of those in common use. The acid appears to me to possess, besides its astringent power, the properties of a stimulant in a remarkable degree; and it is a question whether, in addition to the peculiar action which I know it has of quieting the stomach, and of putting a stop to the violent retching, it does not also exert some influence on the palsied pneumogastric nerves in collapse, and by that influence tend in many cases to give the first impulse to reaction. I have recorded in my note-book a recent case of choleraic diarrhoea, in which the stage of collapse had set in some time before I was called upon to see the patient, but in which the administration of but two or three doses of the nitrous acid mixture proved sufficient to restore the natural warmth to the surface. Did space permit, I could transcribe from my notes very many cases of this kind, all tending to show in the clearest possible manner that the acid has some specific influence upon the system in causing an evolution of internal heat.

Whether the action of the mineral acids upon the eco-

mony be of a chemical nature, or whether their effects in cholera are due to mechanical causes alone, I must leave to those to determine who have more leisure, and are better qualified than myself, to institute the necessary experiments. It is possible, nay, exceedingly probable, as Mr. W. J. Anderson has most ably shown (*ASSOCIATION JOURNAL*, Nov. 4th, 1853), that the introduction of a mineral acid into the system may supply a most important aliment (oxygen) to the impure blood in cholera; but I apprehend the astringent properties of such an agent must be referred, in part at least, to other than chemical changes. All sorts of purely speculative opinions as to the cause of cholera are being promulgated at the present time, which it would be worse than useless to discuss; but with reference to those theories which ascribe the disease to certain electrical conditions favourable to its propagation, or to an excess or deficiency of ozone in the atmosphere, all must allow that neither of these views are incompatible with the notion that the immediate cause of the inordinate and abnormal discharge from the bowels may be the irritation of some fungoid growth, or animalcular deposit, upon the mucous surfaces of the alimentary canal. Believing, then, the fungus theory, as advocated by Mr. Grove, to be as tenable as any other with which we have yet been made acquainted, I cannot help entertaining a rather strong impression that, like sulphur, the nitrous acid may possess a powerful detergent action, and by its caustic power tend to the destruction of the fungoid germs in the *primæ viæ*. Whether this be so or not, it is clear that the acid has the effect of controlling the discharge from the bowels in the most prompt and efficient manner, and that too with much less detriment to the subsequent health of the patient than when cretaceous powders, catechu, or opium, have been largely given with the same intention.

It was seldom, indeed, that I was called upon in 1849, to hasten convalescence by the after exhibition of tonics or other medicines; and this I consider one of the greatest recommendations of the acid treatment.

It is an interesting question whether or not the treatment of diarrhœa by acids was known to the ancients. The great father of physic, in one of his aphorisms, has said, that "Acid belchings supervening upon lenteries, where they were not before, are a sign of mending." And again: "Whether this symptom come spontaneously, or be procured by art, it equally cures the distemper." An old author, who wrote at the latter part of the seventeenth century, in commenting upon these aphorisms, remarks: "From hence it may be inferred that Hippocrates supposed acids to contribute to the cure of loosenesses, because those signs of acidity in the stomach, whether they come spontaneously, or were artificially superinduced, generally signified, according to him, a solution of that disease which is attended with crude dejections." Other old authors have noticed a similar mode of treatment; and I believe the vegetable acids, such as the acetic and citric, have found a prominent place in the prescriptions of some of the ancient followers of the great philosopher of Cos.

Notwithstanding the successful issue of most of my cases in 1849, that were treated with nitrous acid, I do not pretend to say that this medicine is a specific against all kinds of choleraic disease; nor do I imagine that it will alone suffice in every case. Unquestionably, in both threatened and actual collapse, external warmth, stimulant cataplasms, enemata of acetate of lead, and other such auxiliaries, will be found most valuable in the majority of cases. Employed in this way, I think I am authorised by facts in viewing the nitrous acid as one of the most valuable remedial agents that the profession possesses; and I am the more confirmed in this opinion, since a number of patients treated by stimulants, calomels, salines, opium, and other popular medicines, either died, or experienced a most protracted convalescence in my hands; whilst those who were submitted to the influence of the nitrous acid, with but one or two exceptions only, recovered; and that, too, without the slightest apparent detriment to the general health.

In ordinary diarrhœa, or diarrhœa unaccompanied by any

of those symptoms which indicate great prostration of the vital powers, I usually precede the acid mixture by a dose of calomel and rhubarb, with the view of removing any scybala that may be retained in the colon.

The acid I have been in the habit of using is of a reddish brown colour, fuming, and of the spec. grav. 1.212. The manner in which I generally administer it is in the form of a mixture, containing, according to the severity of the symptoms, from 3ss. to ʒi of the undiluted acid, in from ʒiv to ʒvi of any of the aromatic waters; and to this I sometimes add, when there is much restlessness and pain, ℥xl of tincture of opium, but I quite as frequently give the acid without the laudanum as with it. The dose of this mixture for an adult is a quarter part for every two, three, or four hours, according to the degree and urgency of the purging and vomiting. Should the first dose be rejected, as it sometimes will be, in spite of every effort of the patient to retain it, another must be given in about ten minutes after; and in this way it must be persevered in until it remains on the stomach, and the diarrhœa is restrained. The best vehicle for its administration is a cup of thin gruel, suffered to become almost cold. It is always advisable to direct the patient to abstain from taking either liquids or solids for at least half an hour after each dose of the mixture; at the expiration of that time, however, constant and small sippings of gruel or tapioca may be ordered with much advantage. Should there be excessive thirst, a grateful draught may be extemporised by adding a few drops of the acid mixture to a small tumbler of cold water. Experience has also taught me to look upon a dose of the mixture taken fasting every other day, as a most valuable prophylactic measure, by no means to be despised by those who may be constantly or only occasionally in attendance on the sick.

Hitherto I have contented myself with communicating my experience of this remedy to my professional friends; and I have much satisfaction in stating, that every one who has been induced to make use of the medicine has reported to me most favourably of it. My Union colleague, Mr. H. Bursey, of Wandsworth, has, amongst others, informed me that he has given it in a number of cases with the most satisfactory results, and adds, that in the choleraic diarrhœa of children he has found it especially valuable.

In concluding this communication, I must confess that the fear of sharing the discredit which deservedly attaches to those who are constantly abusing public credulity, by extolling, through the medium of the press, some wonderful nostrum, has long deterred me from venturing to publish my views upon the subject I have now, I fear, but very imperfectly handled: nor should I, perhaps, have ever penned this paper, had it not been from a wish expressed by many of my friends, that I should make more generally known my experience of a remedy I had found so valuable an auxiliary in the treatment of the formidable disease at present occupying such general attention.

Whilst I fully concur in the opinion of Dr. Cormack, that the advocacy of uniform and empirical methods of treatment may tend to obstruct, to a certain extent, the progress of rational inquiry, I am nevertheless quite content, in the present state of our knowledge of the disease, to have my cherished remedy placed in the category of empirical medicines, if by its agency I can continue to successfully combat the premonitory diarrhœa in almost every case brought under my notice. Let a case assume ever so formidable a character, I consider, that to be able promptly to arrest the serous discharge from the bowels is to gain almost the haven of a successful issue: and, I cannot help thinking, that if practitioners generally would avail themselves of every opportunity of impressing on those who are likely to become their patients, the danger there is in procrastination, and in neglecting to seek medical advice, whilst the disease is readily amenable to treatment, the greatest good would result, and many a valuable life be saved.

In the more advanced stages of the algide disease, and in cases in which collapse has long set in before medical aid is sought, I am free to confess, that the acid treatment is as

likely as any other to fail in causing reaction. Having no faith whatever in the existence of specifics in medicine, it would be empirical in me indeed to extol this remedy as a never-failing one in cholera. I have nevertheless just that faith in it to believe, that none will be found to repent having put it to the test when once they have been induced to employ it in the earlier stages of that fearful malady—a malady, be it recollected, which has in many districts numbered its victims, not as in this and other favoured places, by mere tens and dozens, but by appalling hundreds and thousands.

Putney, Nov. 21, 1853.

BIBLIOGRAPHICAL NOTICES.

THE SCIENCE AND ART OF SURGERY; being a Treatise on Surgical Injuries, Diseases, and Operations. By JOHN ERICHSEN, Professor of Surgery in University College, and Surgeon to University College Hospital. pp. 944. London: 1853.

MR. ERICHSEN holds the position at University College which has been held in succession by Sir Charles Bell, Mr. Samuel Cooper, and Mr. Liston; and his present work shews him to be not an unworthy successor of these distinguished surgeons. The last work which we recollect as embracing in a short compass the science and the practice of surgery, was that entitled *The First Lines of Surgery*, by the late Samuel Cooper; a book from which many surgeons of the present day have derived the soundest information, and which is still the text-book of numerous practitioners. The later works on surgery, written by English authors, have been chiefly monographs on some special department, or have been confined to the purely operative part of the subject, or have been abstracts of the existing knowledge of the science. A place was undoubtedly open for the publication of a comprehensive work on the theory and practice of surgery, written by a practical surgeon, who, deriving his preliminary information from such teachers as Liston, Samuel Cooper, Syme, and Quain, could illustrate his own views by the experience afforded at a metropolitan hospital. This vacancy, we think, has been satisfactorily filled by the work of Mr. Erichsen now before us; which will not only increase his own well earned reputation as an author and a practitioner, but will reflect credit upon the chair which he worthily fills.

The work is divided into three parts. The first division contains a treatise upon the first principles of surgery, including inflammation, and the general rules connected with operations. The second division contains the special history and treatment of surgical injuries, and their effects; such as traumatic delirium, gangrene, gunshot wounds, punctured and poisoned wounds, wounds of veins, injuries to arteries, of muscles and tendons, and of bones and joints; injuries of the head, of the spine, of the lung, and of the abdomen; burns, scalds, and frost-bites. The third division includes the various surgical diseases, such as abscesses, ulcers, mortifications, erysipelas, pyæmia, tumours, scrofula, syphilis, phlebitis, diseases of arteries, of nerves, of bones, of joints, distortions and other diseases of the spine, diseases of the bursæ, of the head and neck, of the jaws, of the throat, and of the breast, hernia, piles, diseases of the urinary organs, as stricture and calculus, and diseases of the male and female generative organs.

The first chapter is devoted to the consideration of increased vascular action as evinced in determination of blood, and in inflammation, with its consequences, suppuration, ulceration, and gangrene; but these subjects, though well described, offer no opportunity for special remark. In the second chapter, the author takes a practical view of operations; and many of his remarks are characterised by sound knowledge and good sense. The following passage is particularly worthy of commendation:—

“Manual skill and dexterity are necessarily of the first advan-

tage to a surgeon, and he should diligently endeavour to acquire the art of using his instruments with neatness, with rapidity, and with certainty: but, desirable as it doubtless may be to be able to remove a limb, or to cut out a stone, in so many seconds; important, in a word, as it is to become a dexterous operator, it is still of far greater importance to become a successful one. The object of every operation is the removal of disease that either threatens the life, or that interferes with the comfort and utility of existence; and the more certainly a surgeon can accomplish this, the better will he do his duty to his patients, and the more successful will he be in his practice. Success, then, in the result of an operation, whether that result be the preservation of life, or the removal of a source of discomfort, is the thing to aim at. To this, dexterity and rapidity in operating are in the highest degree conducive; but there are various other considerations, equally, or still more necessary, the solution of which can only be afforded by an intimate general acquaintance with the science of surgery and of medicine. The diagnosis of the nature and extent of the connexions of the local disease has to be made; lurking visceral affections must be detected, and, if possible, removed. The constitution of the patient must be prepared for the operation; the best time for its performance seized; and, after its completion, the general health must be attended to in such a way as shall best carry the patient through the difficulties he has to encounter, and any sequelæ or complications that arise must be met by, and must be subjected to, appropriate treatment. These, as well as the simple performance of the operation, are the duties of the operator; and on the manner in which these are performed, as much, or even perhaps more, than on the mere manual dexterity displayed in the operation itself, will the fate of the patient depend. It is well known that the results of operations differ much in the practice of different surgeons of acknowledged dexterity; and this variation in the proportionate number of recoveries cannot be accounted for by any difference in the degree of manual skill displayed in the operation itself, but must rather be sought in the greater attention that is paid by some surgeons to the constitutional treatment of their patients before and after the operation, and to their more perfect acquaintance with the general science and practice of surgery. Indeed, success in operative surgery depends greatly upon the selection of proper cases. The practice of operating in notoriously hopeless cases, with the view of giving the patient what is called a last chance, is much to be deprecated, and should never be done. It is by operating under such circumstances, especially in cancerous diseases, that much discredit has resulted to surgery; for in a great number of instances the patient's death is hastened by the procedure, which, instead of giving him a last chance, only causes him to be dispatched sooner than would otherwise have happened.” (p. 45.)

The mode of administering chloroform recommended by Mr. Erichsen is, to pour about a drachm of this fluid upon a piece of folded lint, about two inches square, and to hold it at a distance of about three inches from the nose of the patient, so as to admit the very free admixture of air with the first inhalations.

“After the lapse of about half a minute, the lint is brought nearer to the patient's nose, to within a distance of perhaps an inch, being never allowed to touch: at the same time, a porous towel is lightly laid over the face of the patient and the hand of the operator, so as to prevent the escape of the chloroform vapour, but not to interfere with the admission of air. During the whole time, it is the duty of the administrator to keep his hand on the pulse, and occasionally to examine the pupils of the patient.”

In discussing the question of amputation, Mr. Erichsen prefers the flap-operation, as might be expected of a pupil of Mr. Liston, who, as is well known, invariably employed that method with great success. The advantages which the flap-operation possesses over the circular are, the greater celerity in its performance, the more perfect coaptation of the opposite sides of the wound, and the greater tendency to union of the stump by the first intention.

In the Chapter on Amputations, Mr. Erichsen gives a tabular statement of the results of these operations at University College Hospital, in 140 cases. From this summary it appears, that out of 45 cases of operation required for injury, 31 cases recovered, and 14 died; and out of 95 cases of operation required by disease, 77 cases recovered, and 18 died; thus the mortality per cent. was in the first

category 31, and in the second, 19. In another table, the comparative results are given from some Primary and Secondary Operations at the same hospital. Of 23 Primary Amputations, 17 were cured and 6 died; while of 22 Secondary Amputations, 14 were cured and 8 died, the mortality being 26 per cent. in the first case, and 36 per cent. in the second.

The Special Amputations are the subject of the Fourth Chapter, and they are all illustrated by very good engravings.

The Chapter on Gun-Shot Wounds is not very copious; and Mr. Erichsen, instead of filling his pages by transcribing the views of others, refers his readers to the well known works of John Bell, Larrey, Thomson, Guthrie, S. Cooper, and Hennen.

The Tenth Chapter is devoted to the Wounds of Veins, and the subject of the entrance of air into those vessels is fully discussed. Mr. Erichsen is already known to the profession from having contributed to the pathology of this dangerous accident; and he alludes to the labours of Majendie, Amussat, Cormack, and others in the same newly trodden field.

The Eleventh Chapter treats of the Injuries of Arteries, and this part of the work is very carefully written, and is full of practical details. We are happy to find that Mr. Erichsen advises the use of the tourniquet in all cases where temporary compression of an artery is required. It is well known to those who attended the practice of Mr. Liston, that that great surgeon discouraged the use of this instrument at one period of his career, and based his objections on grounds which were to a certain extent very plausible; but he subsequently ceased to teach this dangerous doctrine, and commonly employed it himself in his later operations. In fact, however skilful a surgeon may be, and however well versed in anatomy may be those whom he selects as his assistants, the systematic discouragement of the employment of so simple and useful an instrument, might be followed by the most deplorable results, if his advice were acted upon by the general body of the profession.

The history of the means formerly employed for arresting hæmorrhage, and of the establishment of the sound views of practice which now prevail in the treatment of wounded arteries, is described at considerable length; and Mr. Erichsen fully agrees with Mr. Guthrie and other modern surgeons, in the necessity for tying both ends of the wounded vessel in such accidents; and supports his views by arguments which are well known to, and we believe are generally acted upon by the profession.

In the Chapter on Fractures, Mr. Erichsen strongly advocates the employment of the starch bandage, which possesses many obvious advantages over the methods of treatment formerly in use, and he discourages the manufacture of special apparatus in this class of accidents.

"I have no hesitation," says Mr. Erichsen, "in saying, that a surgeon of ordinary ingenuity and mechanical skill may be fully prepared to treat successfully every fracture to which he can be called, by having at hand a smooth deal plank half an inch in thickness, and a sheet of gutta serena, undressed sole-leather, or pasteboard, to cut into splints as required."

"The advantages of the starch bandage in the treatment of fractures, as well as in many other injuries and diseases, consist in its taking the shape of the limb accurately and readily, and maintaining it by its solidity; in being light, inexpensive, and easily applied, with materials that are always at hand. From its lightness, it possesses the very great and peculiar advantage in fractures of the lower extremity, of allowing the patient to remain up, and to move about upon crutches, during nearly the whole of the treatment, and thus, by rendering confinement to bed unnecessary, preventing the tendency to those injurious consequences that often result from these injuries; and, by enabling the patient to keep up his health and strength by open air exercise, facilitating the consolidation of the fracture. In addition to this, the patient will often be able to carry on his business during treatment. By employing the starch bandage in the way that will be immediately pointed out, I scarcely ever find it necessary to keep patients with simple fractures of the leg in bed for more than three or four days,

thus saving much of the tediousness and danger of the treatment."

Mr. Erichsen then describes the mode of applying the apparatus at University College Hospital, which consists in surrounding the limb, in the first place, with a roller; then, in the case of the lower extremity, adjusting a many-tailed bandage smeared with stiff starch; over this are laid splints of thick and coarse pasteboard, well soaked in thin starch. A bandage saturated with thick starch must now be applied; and lastly, this is to be covered by another dry roller, the inner sides of the turn of which may be starched as it is laid on. Thirty to fifty hours are generally required before the starch is thoroughly dried, and this process may be accelerated by the application of hot sand-bags: and when the bandages have become dry, the temporary splints are removed, and the patient may be allowed to walk about on crutches.

Our limits compel us to pass over the chapters on Special Fractures and Dislocations, and also those on Erysipelas and Pyæmia; merely remarking that the two former are abundantly illustrated by engravings, and that the two latter well deserve perusal for the care with which the materials have been collected, and the practical views which they develop.

In the Chapter on Tumours, Mr. Erichsen acknowledges the obligations of the profession to Mr. Paget for his valuable researches into these abnormal growths; and the diagnosis of their different varieties is given with great judgment, the reader being recommended not to trust altogether to microscopical examinations, on the one hand, in forming his opinion, nor, on the other, to neglect this valuable aid in distinguishing the malignant from the non-malignant forms. On the whole, Mr. Erichsen considers that the characters of the cancer-cells, especially of the caudate and fusiform corpuscles, and the admixture of these with other cells, are tolerably distinct evidence of malignant disease; but that the ocular examination by an experienced surgeon will materially assist the diagnosis.

The question of operating in malignant disease is treated at some length, and the opinions of Sir B. Brodie and Mr. Fergusson are quoted on the affirmative side; to whose names that of Mr. Paget may be added, who has stated that the average duration of life is considerably greater in those who have submitted to operation, than in those in whom the disease has been allowed to proceed unchecked. Mr. Erichsen farther thinks, that the introduction of anæsthetic agents into operative surgery, has thrown new light upon the expediency of such operations; and that when a malignant growth can be removed without pain, the patient ought to be allowed the chance of adding a few months to his existence. Cancers of the eye and of the testicle, although very unfavourable for operation, offer no chance of relief or cure by any other means, and whenever practicable, excision should be performed.

In the Chapter on Syphilis, which occupies thirty-three pages, we are able to allude only to the practical views which it contains. In the treatment of the primary sore, Mr. Erichsen recommends the application of the strong nitric acid, one application of which he believes to be sufficient to annihilate the specific character of the sore. In the constitutional treatment recommended, we think the majority of English surgeons will be disposed to coincide. After reviewing the arguments for and against the mercurial plan, and detailing the changes of professional opinion in regard to its efficacy, Mr. Erichsen concludes in favour of a gentle mercurial course, which he thinks necessary for the destruction of the syphilitic poison. His views in this, as in many other parts of his work, are founded on practical experience; and those who attended the clinique of the late Mr. Liston and Mr. Morton at the University College Hospital, are aware that the non-mercurial plan was fully tried by those gentlemen; but yet Mr. Erichsen states, that the patients treated in this manner were very frequently the sufferers from secondary symptoms, and often in a most aggravated form. In his own practice he administers the iodide of mercury, in doses of one grain three times a-day, or the

Plummer's pill, in five grain doses twice or three times a-day, or five grains of blue pill night and morning.

In the Chapter on Diseases of the Arteries, the whole subject of Aneurism is very elaborately treated, but our limits permit us only to notice some of Mr. Erichsen's views respecting the comparative value of the method of ligature and that of compression in the cure of this disease. After doing full justice to the Dublin surgeons for the improvements they have introduced into the treatment by compression, Mr. Erichsen leans to this measure as being upon the whole the least dangerous, and not more tedious. Mr. Erichsen says :

"After considering the relative merits of the two plans of treatment, I think we may conclude that, though in some few cases neither method can be adopted, and amputation is the sole resource, yet, that in others, compression can be employed when it would not be safe to have recourse to the ligature; and that in all ordinary cases of femoral and popliteal aneurism especially, compression should be preferred to the ligature, inasmuch as it is not a more tedious, and an infinitely safer method of cure. At the same time, it must not be forgotten that its success depends very greatly on the continuous care bestowed upon the case during the progress of the treatment."

Of the instruments employed for the purpose of compressing the artery, preference is given to that invented by Dr. Carte, which substitutes an elastic force derived from vulcanised India rubber for the unyielding pressure of the screw, and is therefore adapted for accommodating itself better to the shape of the limb, and is less likely to produce injurious compression.

The Section on the Plastic Surgery of the Face, contains a very full history of the operations resorted to for the repair of mutilations in that region: and the Rhinoplastic and Cheiloplastic procedures are illustrated by some interesting cases which have lately occurred in Mr. Erichsen's practice.

The subject of Hernia is very minutely investigated, and we regret that the length to which this review has already run, prevents us from giving any analysis or abstracts from this portion of the work.

The Chapter on Diseases of the Urethra contains, as might be expected, a very luminous account of the symptoms and treatment of stricture. Mr. Erichsen considers the method by dilatation as the most safe and the most effectual means of curing the disease; but he admits that the introduction of caustics is sometimes advisable. He does full justice to the operation practised with so much success by Mr. Syme, and thinks that in well selected cases it is a most valuable improvement in surgical art.

We regret that our limits forbid us from entering farther into the review of this very comprehensive work. If any objection can be raised against it, it may be urged that the arrangement of the subjects might be advantageously revised, with a view to greater condensation and clearness; and this the author will perhaps accomplish in a second edition. There are also some errors of the pen or press, which are quite excusable in so large a work, executed, as Mr. Erichsen tells us in his preface, amidst the laborious duties of hospital and private practice: but the whole work is a most valuable addition to the literature of surgery, and quite on a level with the requirements of the present day.

CHOLERA: ITS NATURE AND TREATMENT. By EDWARD BASCOMBE, M.D. pp. 26. London: 1853.

DR. BASCOMBE urges upon his readers the great value of the alcoholic tincture of nux vomica, as a remedy in cholera. He calls it a *nervine tonic*, and believes that its action is of a peculiar kind, "not interfering, as is the case with the generality of tonics, with the circulation, it not having the effect of precipitating the action of the great pump, the heart, and involving the circulation generally." After the full operation of an emetic—but in what stage of the disease we are not clearly told—Dr. Bascombe prescribes from fifteen to twenty drops of the tincture every third hour in an alkaline mixture, the formula for which we subjoin. From

what is said regarding "acidulation", we presume that the medicine is taken in a state of effervescence.

Rx Carb. sodæ gr. xv.

Nitr. potas.,

Hydrochlor. sodæ, aa gr. v. M.

This powder is given in half a tumbler of aq. menth. sat., "acidulated with hydrochloric acid"; to which add *immediately*, before swallowing, for an adult, from fifteen to twenty minims of the tincture. The mixture without the tincture is to be given "as often as may be considered necessary in the intermediate time." Dr. Bascombe, speaking of the superiority of the tincture of nux vomica over strychnia, says:—

"From long experience, we have found that the alkaloids of the nux vomica, of the cinchona, and of opium, viz., strychnia, quinia, cinchonina, and morphia, are not the only constituents which give those *medicamenta* their medicinal properties; but that their tonic, antiperiodic, and sedative properties, depend in part upon other ingredients, as also greatly upon the combination in which their alkaloids are presented to us by nature."

In this sentiment, we cordially concur.

The author is fully alive to the urgency and to the nature of the danger which is involved in the great serous discharges; but he thinks too exclusively of repairing the mischief thereby done to the blood, and does not inculcate the better, and generally as attainable course, of arresting the flux, which occasions this mischief. He writes as follows regarding this and other points in the treatment:—

"These two substances (*serum and crassamentum*), from their intimate combination whilst circulating, are necessary to each other. Should the diarrhoea, therefore, inordinately drain off the serous portion of the circulating medium, containing the salines so necessary to the blood's fluidity, by which its integrity would be spoiled, the tar-like crassamentum left being unfit for vitality, we must supply its place by not only giving by the mouth, but through the intestines, the saline preparations similar to those so extensively and so successfully used by Dr. Stevens, who was the first propounder of their signal efficacy, as has been confirmed by subsequent experience. These preparations, with the addition, according to circumstances, of the alcoholic tincture of the nux vomica, being assiduously administered, we must patiently await the result of our operations; nature, thus aided by our judicious endeavours to counteract the tendency to death, being sure to do her part in eliminating or overcoming the *virulent influence* for the furtherance of a happy result in the restoration to health.

"As a powerful adjunct to the foregoing treatment, we must not omit the recommendation (which cannot be too perseveringly attended to), namely, of friction downwards, with two parts of lin. saponis and one of ol. terebinth., along the entire spinal column, by which simple means we, by stimulating, give tone to the nerves, so plentifully supplied therefrom, to the thoracic, the abdominal, and pelvic viscera, and which are so immediately implicated. Meanwhile, the patient should be kept warm by proper covering, and there should be a *free admission of air*. As regards nourishment, until the alimentary canal be in a condition to appreciate or assimilate it, we need not have much care. Gelatinous preparations, with beef tea, will be found, however, to be the most appropriate.

"Trusting in this formidable malady to small doses—alterative as they are called—alterative (?) of calomel and opium, is worse than doing nothing—a trifling with human life, independent of the otherwise injurious effects of the opium, it notoriously having the effect of *blocking up* the secretions, especially that of the liver; and as to alcoholic stimulation, I deprecate it as being positively *murderous*; for how often have I witnessed poor wretches, while being drenched with brandy, champagne, gin, etc., crying out for God sake to give them no more, for they were burning up inside! and when they have expired, a *post mortem* (in which I have been sometimes engaged to the number of eleven before breakfast) has exhibited the engorged condition of the abdominal viscera, with the omentum spread out resembling a piece of a soldier's jacket, so infiltrated was it with blood." (p. 24.)

We agree with the author in thinking that *to trust to calomel and opium* is to trifle with life; but we are equally convinced that both of these medicines ought to be given in moderation in a considerable number of cases of cholera. Alcoholic stimulation *in excess* is, we admit, "murderous";

but there are circumstances in which its judicious use preserves from fatal syncope, and affords time for the use of other measures. As to the engorged condition of the abdominal viscera, it is the result of the congestive character of the disease, and of the stagnation of inspissated blood in the capillaries: it is an appearance which is found in those who have been treated without, as well as in those who have been treated with stimulants.

Dr. Bascome gives the following formula for the saline enema referred to in the text:—

R Carb. sodæ et
Nitr. Potassæ, aa gr. x.
Hydrochloratis sodæ 3 ss.
Aquæ menth. sativ. (c. mucilagine) ʒxij. M.

He proposes that this should be administered every half hour (or oftener, if it be retained, and should the case be urgent), at a temperature of 96° or 100°.

The principal point in this pamphlet is the testimony in favour of *nux vomica*. The defect in the pamphlet is the indefinite way in which the condition of the patient and the stage of the disease is explained in connexion with the treatment advised. Practitioners do not require more remedies for cholera; but they stand in need of more wisdom in the employment of those which they possess; and, till authors explicitly describe the exact conditions under which they have adopted certain measures, or under which they recommend them to be adopted, individual experience cannot, we fear, be made available to any great extent for the general instruction of the profession.

CHOLERA AND ITS TREATMENT. By Dr. AUZIAS TURENNE. [Translated by F. BATEMAN, M.D.] 8vo., pp. 12. London: 1853.

The author, without excluding other means of treatment, relies principally upon the use of water. He says:—

"I have often heard of persons attacked with cholera, and who, being without assistance, were induced by a salutary instinct to drink incessantly until cured.

"Experience proves that the action of the choleric miasmata resembles greatly that of a poison. Now, what is the treatment of poison? First. To decompose it, and, if we cannot do that, to eliminate it. Second. To treat the organic disorders produced by its action. Now, we do not know the counterpoison of the choleric miasmata; we ought then to seek their elimination by giving liquid in every possible manner. With regard to organic disorder, they, as well as any violent reaction, are prevented by the sedative and antiphlogistic action of the water.

"When the urine was slow in appearing towards the close of the disease, I have often excited its secretion, by the application of sinapisms or blisters in the region of the kidney. In order to obtain the same result, I have successfully used injections of a small quantity of tepid wine, or tepid alcoholised water, into the bladder, without having occasioned the least cystitis. These injections, by exciting the kidneys to secrete urine, have the same effect on the bladder, as excitants on the stomach, which excite the secretion of bile, as pepper on the mouth, which excites the secretion of saliva. Thus to recapitulate—give liquids, then nourish gradatim with light broth and milk in large quantity, passing then to more substantial nutriment, I recommend especially cold milk, taken in large quantity, as soon as the patient is better."

As to recoveries from cholera, we must always bear in mind that it is a paroxysmal disease; and that the stage of collapse has a tendency to terminate in a return to health, just as is the case with the cold stage of a common ague.

INTRODUCTORY LECTURE at the Opening of the Session of the Chatham Street School of Medicine, Manchester, Oct. 3rd, 1853. By GEORGE SOUTHAM, F.R.C.S. pp. 24. Manchester: 1853.

THIS is a sound and seasonable address. Orthodox medicine is defended, and charlatanic systems exposed. Religion, good morals, and polite literature, are shown to be requisites in the formation of the character of the enlightened and useful medical practitioner. The following is good advice;

and we would extend its application even to the busiest of the busy, for none require more than they do the sustenance and bracing of those mental tonics which Mr. SOUTHAM recommends:—

"There are periods in a professional man's life, especially at its commencement, when his time is not fully occupied. A large portion of it may be devoted to the improvement of his medical knowledge; but the mind requires relaxation, which it seeks from a variety of sources. If he enter into the amusements of the day, he will find they will often interfere with the duties of his calling. But a well regulated mind has such resources within itself, that it can find recreation in solitude from the elegant writings of Addison, Johnson, Milton, and other classic authors; and can appreciate the beauties of Shakespeare without the exciting attractions of the theatre." (p. 8.)

REPORTS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON.

SATURDAY, NOVEMBER 12TH, 1853.

FORBES WINSLOW, M.D., President, in the Chair.

PATHOLOGY AND TREATMENT OF CEREBRAL DISEASES. BY R. H. SEMPLE, M.D. [Dr. Semple's Paper is published at p. 1051, of this number.

A discussion followed the reading of the paper, in which Dr. Fuller, Dr. Theophilus Thompson, Dr. Druitt, Dr. Sibson, Mr. B. W. Richardson, and the President, took part. The difficulty of diagnosis was the topic which principally engaged attention.

MONDAY, NOVEMBER 14TH, 1853. [PHYSIOLOGICAL SECTION.]

WHY DO FLUIDS MOVE ONWARDS IN THE URETER AND THORACIC DUCT? BY B. W. RICHARDSON, ESQ.

Mr. RICHARDSON proposed the question; but he did not attempt to solve it. He thought that the inquiry was novel, and demanded the attention of physiologists. The anatomical relations of the parts, and the dynamical law of gravitation, did not explain the mystery.

DETECTION OF IODIDE OF POTASSIUM IN THE SECRETIONS. BY C. COGSWELL, M.D.

Dr. COGSWELL, by a series of experiments showed that starch with fuming nitric acid is the most delicate test for manifesting the presence of the salt in the excretions.

VOLUNTARY MUSCULAR FIBRE ATTACHED TO AN ADVENTITIOUS GROWTH. BY DR. EDWARD SMITH.

Dr. E. SMITH, exhibited a bony growth in the fibrous tissue of an old pleuritic effusion, which had the rare peculiarity of the true attachment of voluntary muscular fibre. The patient from whom it had been removed was a colonel in the East India Company's Service, and had spent forty years in India. He had also suffered from pectoral affections from the period when he was six years of age. On a *post mortem* examination, the pleura pulmonalis was found attached throughout its whole surface to the ribs and the diaphragm, and this plate, having the size of four inches by five inches, occupied a perpendicular position on the right side, terminating below, near to the diaphragm. The cause of the attachment of the muscular fibres was the point of interest. The muscular fibres were not presumed to be a new growth proceeding from any change in the effused lymph, and since the pleura would intervene between the diaphragm and the intercostal muscles, it was difficult to imagine how any attachment of these muscles could have been effected. It was quite clear, that this growth was not a part of the original attachment of the muscle to a rib; and, assuming that the pleura had been destroyed, and the fibrinous deposit thus permitted to approach the muscular structure, it was not even then easy to show how any true tendinous attachment should connect the body of the muscle with the adventitious structure. Dr. Sibson had attended the *post mortem* examination, and Professor Quekett had examined the structure.

DOG WITHOUT A SPLEEN. BY E. CRISP, M.D.

Dr. CRISP exhibited a dog, the spleen of which was removed two years and a half since, by Dr. Leared, of Finsbury-circus. The animal was in good condition, and did not appear in any way to have suffered from the loss of the organ. The blood, which was exhibited under the microscope, presented no abnormal appearance.

WEIGHT AND FORM OF THE HEART, DIAMETER OF THE AORTA,
AND SIZE OF THE BLOOD CORPUSCLES IN THE VERTEBRATA.

BY EDWARDS CRISP, M.D.

Dr. CRISP brought forward a great mass of valuable facts, and illustrated his subject by numerous preparations and drawings. We regret that we have not space at our disposal for an abstract of this valuable paper, and of the remarks made upon it by Dr. Winn, Dr. Snow, Mr. Richardson, Dr. Chowne, Dr. Leared, and others.

SATURDAY, NOVEMBER 19TH, 1853.

FORBES WINSLOW, M.D., President, in the Chair.

RESECTION OF THE KNEE JOINT.

BY G. M. JONES, ESQ., OF JERSEY.

Mr. JONES stated that he had six times performed the operation of resection of the knee joint. All had been successful except one, which had died from epidemic dysentery. He (Mr. Jones) had brought over two successful cases for the purpose of ascertaining from two or three leading surgeons if the operation ought still to be performed. One patient, 20 years of age, had the bones excised, and the patella removed twelve months ago, and is now able to walk steadily with a stiff knee without limping; to walk six or seven miles at one time, and to mount ladders in carrying on the business of a painter. The disease was strumous. The other is 13 years of age, and had the same operation performed six months ago, except that the patella was not removed. His limb is stiff, and he has now dislocation of the opposite hip joint, but yet is able to move about with the aid of sticks.

The PRESIDENT congratulated Mr. Jones upon the success of his operations; and tendered to him the thanks of the society for his interesting communication.

THE FIBROUS CONSTITUENT OF THE BLOOD IN RELATION TO
DISEASE. BY B. W. RICHARDSON, ESQ.

[We have received this paper for publication.]

Mr. Henry Lee, Dr. Crisp, Dr. Routh, Dr. Camps, and Dr. Snow commented upon and lauded Mr. Richardson's paper.

LIVERPOOL MEDICAL AND PATHOLOGICAL
SOCIETY.

OCTOBER 6TH, 1853.

JOSEPH DICKINSON, M.D., in the Chair.

CASES OF FATAL POISONING BY CENANTHE CROCATA.

BY J. B. NEVINS, M.D.

The actual production of death by our indigenous herbs is not common, though serious effects for a time are frequent enough. The following cases are therefore not without interest.

On the 9th of September, 1853, four children ate some roots which had been dug up in clearing a ditch. They resembled small dahlia tubes, possessed a strong umbelliferous smell, and a bitter, slightly disagreeable taste. They were recognised as being the fleshy roots of the *anathe crocata*, hemlock water dropwort, which is reputed to be one of the most poisonous of our native herbs, and grows abundantly in the sides of ditches, and on damp hedge bottoms, in the neighbourhood of Liverpool, and many parts of Cheshire.

The children ate the roots at 2 P.M., and, about half-past 6 P.M., they were brought to the Royal Infirmary, and admitted under the care of Dr. Turnbull. At that time, one of them, a boy, at the age of casting his milk teeth, was perfectly insensible; the face was livid and turgid. He had previously vomited blood, and bloody mucus oozed from his mouth after admission. The prominent symptom was *violent convulsions*, solely affecting the *flexors throughout the body*. The trunk was powerfully bent forwards; the hands were firmly clenched, even after death; and the jaws were so rigidly closed, that some of the front teeth were broken out in opening the mouth to introduce a stomach-pump. The spasmodic contraction sometimes gave way for a few minutes at a time, but the extensors were never affected. The respiration was spasmodic till death. The pupils were at first contracted, but afterwards dilated until death: they acted very feebly under the stimulus of light. The pulse was almost imperceptible. There were no involuntary discharges. This state continued until death, which occurred about twelve hours after taking the poison. There was no return of consciousness, and the spasmodic contractions continued, with slight intermissions, as long as he lived. There was no vomiting after his admission; and the stomach-pump removed nothing but a portion of a blackberry.

Treatment. Cold was applied to the head, and diffusible stimulants were administered internally.

Quantity Eaten. As well as could be ascertained, he had eaten only one root, about the size of a man's thumb; but he had also eaten "a handful or two of the berries": they were dulcamara berries.

Examination of the Body, thirty-six hours after death. The contraction of the flexors was permanent. The hands were firmly clenched; the skin of the face and hands, and especially of the fingers, was very dark; the stomach and duodenum were empty, and perfectly free from any signs of either inflammation or congestion. There was no effusion of blood, and only one or two insignificant ecchymoses. The veins of the head were very slightly congested. There was no effusion in the cerebral ventricles.

Another child was also insensible and convulsed like the first, and appeared to be equally ill; but he recovered under the use of the same treatment which had been without success in the first case. The next day, he merely complained of some soreness of the stomach. The quantity eaten was unknown.

A third child merely complained of an abdominal pain, and had no cerebral symptoms. It quickly recovered.

Several cases of poisoning by the roots of this plant, eaten by mistake for celery, are recorded in Woodville's *Medical Botany*. "Three soldiers ate, or rather tasted, the roots. Without previous notice or sickness, one of them was seized with convulsions. In spite of almost immediate treatment, he died presently. The two others were soon seized in a similar manner: one of them died; the other recovered, after being bled, and having a vomit, which was forced down with great difficulty, on account of his jaws being as it were locked together. Neither of these two had any sickness previous to the emetic being given."

Eight boys ate plentifully of the roots, which they mistook for water parsneps. In about four hours, one boy became convulsed, and died. Next morning, four others died in a similar manner; a sixth boy became maniacal for several hours; a seventh lost his hair and nails; and the eighth escaped unhurt. Other cases are mentioned, in which convulsions were the chief symptoms; and two only are narrated in which there was vomiting.

It appears, therefore, that convulsions are universally produced by this poison; and that a small quantity of the root suffices to cause death, which generally occurs in about twelve hours. The limitation of the convulsions to the flexors is not noticed in any of the cases recorded by Woodville; but vomiting is specially mentioned as absent in nearly every case. Now, bloody vomiting was a prominent symptom in the first fatal case which I have recorded; but it must be remembered that the child had eaten one or two handfuls of dulcamara berries, which frequently cause vomiting. This was, therefore, a case of mixed poisoning; and probably the vomiting was independent of the *anathe*. In the two cases mentioned by Woodville, in which vomiting was present, nothing is said about any other poison than the roots having been taken; but the sufferers were children. The dulcamara berries are ripe and tempting at the time when these cases chiefly occurred; and it is not improbable that they also might have taken these berries as well as the more deadly root.

Dr. TURNBULL, after some remarks upon Dr. Nevins's paper, stated that, in consequence of the known activity of this herb, he had thought it might possibly be useful as a narcotic in phthisis; and had had an extract made from the root of the *anathe*. It however produced depression and purging, but no alleviation of the cough. He had also employed an extract from the *seeds* of the *phellandrium aquaticum*, which had acted slightly like a stimulant resinous expectorant; but he did not lead the society to think that it had been of much service.

EDITOR'S LETTER BOX.

GRATUITOUS MEDICAL SERVICES: PHYSICIANS AND GENERAL PRACTITIONERS.

LETTER FROM JOHN BARCLAY, M.D., M.R.C.P., TO THE EDITOR.

SIR,—Nearly every medical question has two opposite aspects in which it may be regarded; and in the matter of gratuitous advice, whether at hospitals and dispensaries, or at the houses of medical men, the opinions of one party have been pretty well heard. But the physicians of the provinces, however much, numerically, in a minority, are as much an integral part of the Association as either of the other branches into which the profession has naturally subdivided itself; and I therefore beg you to allow my little protest to be heard against the covert attack which is being made on the body to which I belong, in the crusade which is now going on against the practice which has existed in most places, of physicians giving advice to the poor.

And let me here make it to be most clearly understood, that I speak of *bona fide* physicians. I utterly abhor the unholy traffic between certain so called physicians and druggists. Were they really physicians, members of the College, their admission oath would prevent such disgraceful advertisements as those lately quoted in the Journal; and every well-wisher of the profession must long for some power to be created sufficient to drive such men as the writers of them from out its pale. Further, I do not call him a physician who breaks his fee, and thus enters the lists as a general practitioner, who will take 5s. when he cannot get his guinea: and lastly, to make all clear, I desire to define the "poor" as the really needy, those who cannot, without great and serious deprivation of the necessities of life, scrape together a guinea to pay for advice; and those to whom it is utterly impossible—the victims of the counter-practice of the druggist.

In discussing the subject with a surgeon the other day, he threw a deal of light on the motives of the present agitation. "How," said I, "is a young physician to gain experience, if he do not practise among the poor for many years of his life?" The laconic, but awful reply, was: "There *should* be no young physicians." This I hold to be at the root of the movement; and I think a little investigation will show that the chief complainants are not the so called sufferers, but those who advocate the "one faculty system", and who desire to constitute themselves physicians, and to assume the functions which I hold they should have sought at the hands of the College.

Physicians are paid by fees; the lowest fee is a guinea. If, therefore, only those who can afford to pay a guinea for his opinion are to have it, his practice must be confined to the rich, or the poor must content themselves with some other physician's opinion at a public institution. No one, who goes through the drudgery of seeing out-patients at a hospital, could allow that this would be satisfactory. The young physician is not the man who gets the hospital appointments: on the contrary, his seniors generally do all in their power to prevent him reaching the same vantage-ground as themselves. If he had not the happy resource of relieving the poor, and thus acquiring experience, the wishes of my surgical friend would be realised, and the race and name of physician be together extinguished.

My next assertion is, that the poor should find the medical man a blessing, and not a curse. Illness is in itself almost overwhelming to the man who earns his daily bread by labour. How often have I seen servants, with their £8 or £9 wages, deprived of £2 or £3 of it in a surgeon's bill, which their master or mistress would not pay. It is surprising indeed what the pressure of sickness will squeeze out of a man. The few hoarded shillings, or the pawnbroker's price for some little article of luxury or of show, often find their way into the surgeon's pocket, under the pressure of the County Court, or a threat of being brought within its jurisdiction. Labourers and trades-workers, with their 12s. or 15s. a week, a wife and three or four children to bring up, who pay their midwifery fee of 10s. 6d., which occurs with annual regularity—such men deserve to have advice for trifling ailments from those who are willing to give it, in place of the wretched devisings of the druggist or the quack to whom they are sure to apply. I believe the only effectual blow which can be struck at the pernicious counter-practice of the druggists is to afford every facility for the poor receiving advice of a proper kind. There are probably in every town some two or three medical men struggling into practice, or just barely qualified, whose charges hardly exceed those of the

druggist; but the poor will not employ them until they are so ill as to be laid up at home. For minor ailments, their application is to the physician on his gratuitous day, or to the druggist, or to quacks. There is, too, a class—a very large class—for whom physicians are in the habit of prescribing as a charity, who very often find a very grievous burden in a surgeon's bill. I speak of poor curates, poor dissenting ministers, schoolmasters, clerks; I do not suppose any one will hesitate to admit their claims.

It is my belief that a "practice" is not often made by gratuitous advice. People do not value it so much as what they pay for; and so in after life, when severe illness requires a consultation, probably the very person who has formerly been a charity patient sends for another physician. The tangible reward acquired by the physician is his *experience*, which can only be got by treating a large number of cases. And this experience is what will ultimately tell with the public. They will rather consult the man who has treated 20,000 paupers, than him who has only treated 2,000 ladies and gentlemen. It is not the class whom he prescribes for gratuitously who ever find themselves able or willing to remunerate him; therefore, in relieving their necessities, he does no harm to the general practitioner, but assists and relieves the parish surgeon, the club surgeon, the dispensary, or the county hospital.

I have said that the physician is remunerated by the experience he acquires. He is so, fully; and it is a bargain which both giver and receiver perfectly understand. But there is a far higher and a far nobler gratification for him. It is mocked at, and called cant and hypocrisy; but the feeling is implanted in most human breasts, and it warms as it receives the blessings of the poor—it enables us to enjoy the luxury of doing good. There is also another source of gratification; it is that of having done our duty to the best of our poor ability. The calling of the medical man is the most god-like of all the professions. He is a pure benefactor, and no suspicion can be entertained of his motives: he is a benefactor, and this beneficence is his duty. I lament, sir, that the high calling of the physician should need my paltry aid against such assaults as have lately been directed against it.

The physician should, for his own sake, throw every obstacle in the way of the abuse of his kindness, by inconvenient hours, by close inquiry into circumstances, and the careful discrimination of cases of real need from those of imposture and meanness; and he will often be called on to send cases away peremptorily, at the risk of doing an act of unkindness; but still I hold that it is a part of his duty to relieve those gratuitously who desire his advice, and who cannot pay him his fee; and who are likewise willing to show their sincerity in desiring it by surmounting the obstacles his ingenuity may have suggested to prevent the abuse of his kindness.

The grand mistake of the present day is, that the physician has in too many instances put himself in a position antagonistic and directly competing with the general practitioner. It is nothing else than an abomination for the physician to take so few fees when called in in consultation, that the family is induced to consult him alone on future occasions. When such a thing does occur, it is the physician's duty almost invariably to refuse it; otherwise the general practitioner can never wish to meet him again. On the other hand, the jealousy of the general practitioner is in many, I trust in most cases, uncalled for. Consultations should be friendly meetings for the benefit of the patient, not hostile conferences for the advantage of either physician or surgeon.

Another evil very prevalent is the too great frequency of consultations,—daily, or even twice a day, putting the surgeon in the place merely of the compounder of drugs, and taking the entire responsibility out of his hands. The meetings then cease to be consultations; and the general practitioner feels himself put in an inferior position, which is galling to him.

I believe the much more friendly feeling which exists between practitioners in rural districts and the physicians who reside in the county towns, arises from the feeling of security they have that there is no possibility of the physician becoming his rival in the confidence of his patient. I believe, also, that the more pains the physician takes to secure this confidence to the surgeon, or to restore it when waning (which a word judiciously spoken will often do), the more pleasant and the more frequent will the intercourse become.

I do not believe that ethical rules—except very general ones—can do any good. It is impossible to instil gentlemanly feeling where it is originally lacking. The only law which can guide us into pleasant intercourse with each other is the old golden rule, to "do as we would be done by"; thinking no evil

of our neighbour's proceedings, and taking very good care not to transgress his border ourselves.

I repeat, the physicians are a very small minority; the *bond fide* physicians are not, I suppose, more than one in six or seven of the profession: but I trust there is too much good feeling to allow of any injustice being done to them. Physicians have to wait long for remunerative practice; and, while gaining experience, I do not believe one case in a hundred is taken from the regular surgeon's practice.

In conclusion, I beg to say, I will yield to no one in my anxiety to support the dignity of the profession in all its branches; which is best to be done, not by a paltry struggle after money, but by cultivating a good understanding, not only between surgeon and physician, but also between the patient and his ordinary attendant.

I trust my warning voice may not fall unheard by provincial physicians. Our place is rightly that of consultee: by leaving it, and seeking family practice, we enter the lists with the general practitioner, and make *him* our enemy, who should have been our friend.

Apologising for the space I have occupied; I am, etc.,
JOHN BARCLAY.

Friar Lane, Leicester, November 8th, 1853.

A WORD FOR "ADVICE GRATIS".

LETTER FROM SAMUEL KNAGGS, Esq., TO THE EDITOR.

SIR,—I am not one of those who give "advice gratis"; nevertheless, let me ask you to read this letter, and, if you think fit, to publish it. The columns of the medical press have for a long period been open to an agitation against gratuitous advice, and much truth has been uttered, not however in some instances undisfigured both by partiality of sentiment and warmth of expression. The subject is one of very great importance alike as relating either to individuals, or to the whole body of the profession; and as it seems to me from what has been written, that the root of the evil has not been sufficiently called attention to, I am induced to pen these few lines.

Is gratuitous advice under any circumstances admissible as a matter of principle? Now the only argument of force that has been brought against this, rests in the statement that no other profession will work gratuitously, and the legal is that usually fixed upon as the case in point. Granting this to be correct (which, however, I much doubt), still the instance is not apposite; for the legal profession has only to remedy abuses which may be prevented, whilst the *medical* is called upon to relieve misfortunes which no human eye can foresee or guard against. In deciding this fundamental question, we ought not to lose sight, in over anxiety for ourselves, of the motives which should actuate the practitioner of medicine; he has chosen his profession, it is to be hoped, not from the love of gain, for if so, he has widely erred; not alone from the love of science, for this would be beneath him; but from a desire to occupy a station honourable to himself and useful to society, in which all the higher intelligences of the head, and nobler qualities of the heart, are brought into active employ: in action it becomes his privilege as well as duty to relieve disease, to administer to necessity, and by these means to procure a well merited subsistence for himself and provision for his family.

Without for a single moment questioning the proposition that richly endowed institutions (capable of so doing) ought to remunerate medical men for their services, still we shall all be able to call to mind instances within our own limited experience, where such provision could not be made without materially circumscribing the benefits of the charity; for it should not be overlooked that unless the remuneration bear a fair proportion to the service rendered, the action is gratuitous, though only equivocally so. Surely, in such cases, medical men may be allowed to recognise in the body, as private individuals are free to do without either comment or censure, the call upon their charity, and to give (what stands to them in the place of money) their time and talents to the furtherance of active benevolence. I do not imagine that you, sir, or any of your readers, will hesitate to acknowledge the perfect right so to act, under such circumstances; and therefore I shall assume as a conceded point, that *gratuitous advice is both justifiable and praiseworthy, so long as it is confined to its appropriate sphere!*

Wherein, then, lies the objection to gratuitous advice? Is it not because it is found in practice that the individual who gives his gratuitous services to the institution, and he who gives them at certain hours to the public in the morning, is imposed upon by the recipients of relief, and that thus an already overloaded pro-

fession is impoverished by relief being afforded to those who are really in a condition to pay their medical attendant. It is, therefore, indiscriminate charity which calls for censure, and which it will be well for the profession if possible to arrest.

How is indiscriminate gratuitous advice to be put a stop to? Now with reference to this, the conditions both of donor and recipient require separate consideration, with a view to a correct estimate of the difficulties to be contended with. Thus it will be apparent that the only course likely to avail as regards the *applicants*, is to subject each one to such careful scrutiny by proper officers, as shall effectually prevent persons of good means practising such imposition; and this in most country towns might, I imagine, be tolerably easily and effectually accomplished: our experience shews that we cannot safely rely either upon the honesty of the applicant, or the consideration of the governor who fills up the recommendation for the hospital. But the way to prevent indiscriminate relief being given by medical practitioners, is a point not to be so readily disposed of. If it be correct in principle to give gratuitous advice at all, then has every professional man, I think, an undoubted right to receive his quota both of the benefits and the pleasures resulting therefrom; and surely he has good cause to feel aggrieved if he finds that in the part wherein he resides, a large institution sweeps away those very cases which he would delight to observe, and upon which, if he be young, he should be entitled to expect to build his hopes of practice. May he not well complain, if in the attempt to direct some of those who throng the infirmaries to himself, by offering to give advice at certain hours upon the same terms, he discovers himself stigmatised by his peers, as having done something which he really ought not to do? I cannot enter into the feeling that does practically debar the youthful medical aspirant from settling in the towns of our island, excepting in the stereotyped capacity of son, partner, or house surgeon. The country practitioner is enabled to work onward in his early career (though his gains may not be great), deriving solace from the knowledge of the services he is daily rendering to his poorer fellow-creatures, proving that he is not leading either a motiveless or useless existence. Far otherwise is it with his brother of the town; here is the same willingness to devote his youthful energies to labours congenial to his feelings, even though not directly remunerative to himself; but, owing to the present monster system of monopoly, he must consent for years forsooth, to lie by and rust, unless through interest, or some happy stroke of fortune, he be accidentally precipitated into practice.

But, sir, I have yet to learn, with every respect for the officers of our infirmaries, upon what sound ethical rule they rest their claim to the monopoly of gratuitous advice. It is doubtless desirable both to ensure a high standard, and, for other obvious reasons, that the staff of officers who attend upon the urgent responsibilities of internal hospital practice, should be limited; but why should not every legally qualified practitioner who is willing to give his time, be permitted, at certain specified hours in an appointed place, to see and prescribe for those out-patients who would *prefer* to have his opinion, but cannot afford to pay for it? By such regulation the *great name* would yet be in the greatest request, the deserving patients could be sifted from the undeserving, and the deadliest blow would then be aimed at indiscriminate advice, by purifying the source from whence it sprang.

It may be objected that as the *matériel* is found by the subscribers, they are entitled to dictate the terms upon which the medical officers shall be appointed. This may be very true if the medical services are paid for; but if the profession accords them gratuitously, it is clearly at liberty to specify on what condition they may be so given, and is bound to take care that in thus doing, the interests of the majority of its members are not injured for the sake of the privileged few.

I can understand that those individuals who have succeeded by dint of perseverance and good fortune in obtaining what is termed a good practice, should be inclined not only to retain this for themselves, and transmit it to their children, but also that they should be wishful to close up those avenues which are apt to lead their young opponents into footpaths of dangerous proximity; I can equally well enter into the feelings of disgust and indignation which must fill the breasts of those who are starting in the race of life with high aspirations and "noble thoughts elate," when they for the first time experience the deep injustice of this, to them, almost paralysing system. Could it relate its own workings, it would unfold a tale of shattered hopes and ruined expectations which were once deservedly bright as the beams of the midday sun; it would tell of jealousies and heartburnings innumerable by its means fostered in

the bosoms of those who, but for it, would have been linked in a common brotherhood; a system, devised to carry comfort and assistance to the hearths and homes of thousands of our poorest countrymen, made by its wretchedly unfair organisation an instrument to impede the progress and torture the minds of those who might otherwise be its ablest supporters.

Now, sir, I am free to admit that I do not approve the "advice gratis" system, on account of the difficulty of discriminating the deserving from the undeserving, and the facilities it offers for abuse; and in all cases myself, when I have thought a patient above the station it was intended to include, I have refused to give the advice sought. If the question be freely and fairly met, I for one shall only be too happy instantly to give up the "advice gratis"; but I cannot see how the profession can otherwise expect to arrest or mitigate an evil, which is solely resulting from an internal impropriety of arrangement, which ought never to have been allowed. I am, etc.,

SAMUEL KNAGGS.

Huddersfield, Nov, 1st, 1853.

THE UNPAID MEDICAL SERVICES EXACTED BY THE STATE.

LETTER TO THE EDITOR.

SIR,—I am a very young member of the Association, though a few grey hairs begin to tell me I am not very young in life. I joined the Association, because I wished to see the whole of our profession united. I could bring no one to the ranks but myself, so I brought myself; and I am ready to do my duty as a good and faithful soldier. Yet a soldier, however good and faithful he may be, can do little as an individual; the victory is gained by the concerted action of many individuals. One person may plan a battle; the masses must fight it; but, to win the battle, the masses must act strictly in concert, as one man. Now, it is because our profession have never acted in concert, that we have never won a fight. For the same reason, every year finds us with some new duty or obligation imposed upon us, which new duty we are to discharge gratuitously, for, it is said, the public good. There is no other profession or calling in life so honoured as our own; the services of all others are bought at a price; our money value has yet to be discovered. In the law, from the Lord High Chancellor to the Clerk at Petty Sessions, all are, in their several stations, well paid, and have their duties well defined. In the church, from the Archbishop of Canterbury to the humble curate of St. Germo, all have well defined duties, and, for the most part, they act well in concert; for, however much the church is divided "on particulars", they act well together "in generals"; and, as a body, they are well and largely paid.

But, in medicine, it is the high places, and the customs of those who occupy those high places, that have blighted, are blighting, and, so long as the customs remain unchanged, ever will blight, the prospects and fortunes of our profession. Our metropolitan hospital staff, both surgeons and physicians, together with the staff of all the infirmaries and dispensaries, all the provincial hospital and dispensary staff, are not only discharging duties—duties onerous and most important—gratuitously, but all those offices, both in the metropolis and provinces, are most eagerly sought after, advertised for, canvassed for, and every species and form of personal and social interest is employed to obtain what to the public must seem, from the trouble and anxiety taken in the matter, a perfect medical *El Dorado*. The public do not see why medical men are so eager for those appointments. The public, as a body, know nothing of the fees received from pupils and apprentices to those large institutions; but they do see that, when once appointed to those institutions, the holders of those appointments obtain a wider celebrity, and that they see a vast number of cases, which gives them experience; experience mostly gives tact and celebrity; experience and tact bring the golden harvest.

The number of those who hold hospital appointments is, in comparison to the whole body of the profession, very small; but the effect of the advertising, canvassing, and gratuitous system, is felt by the remotest and most humble village practitioner in our country. It is the poisonous essence in our poor-law medical system. It is the same power that keeps alive the often and justly denounced club system. It is the same power that throws the exclusive medical charge and cost of all between the poor-law class and the club patient on the medical man. Let him refuse his aid, and woe betide him! But let us hear the argument of the squire and rector of his parish. "It is a part of your duty, sir, to attend those poor people. We see Mr.

B. and Dr. S., men of high standing, giving aid to all who ask it, and attending the hospital day by day; and yet, sir, you refuse to see a few poor for nothing. It is cruel, sir, and unjust. Must those poor people die for want of medical care?" In vain you urge your want of means, that the Poor-law Board do not pay you the cost of your medicine, that neither the squire nor the rector support the village club or the village doctor. Refuse the aid sought, and you are denounced. It is the custom of the profession to give gratuitous aid. Mr. B. and Dr. S. give it, and so must you.

Our profession has, too, been much honoured by the legislature; it has imposed on us high and responsible duties, but no pay. Not long since, we were called on, "for the public good", to give, in every case of death, a certificate with particulars concerning it: we are now called on to give certain very precise certificates concerning vaccination—"both gratuitous"; but, from the Registrar General, down to the Registrar of sub-districts, the legislature provides an adequate remuneration for their portions of the same work. But the most paternal care has been taken of the Poor-law medical officer. He contracts to attend duly and punctually upon certain poor persons receiving medical relief; to keep a list of those whom he attends; to transmit the same once a week to the guardians; and to give certain information when required; and for all this he is paid not quite the cost of his medicines. In addition to this, he has, under certain heavy penalties imposed by the lunacy act, to attend upon, punctually, every pauper lunatic in his district chargeable to any parish, and to prepare and sign a list stating all particulars of such lunatic, and transmit the same once in every three months, to the Clerk of the Peace, to the visitors of the County Asylum, and to the Commissioners in Lunacy, and to keep a fourth copy himself. Under the sanitary laws, the medical officer is endowed with extraordinary power, he is to make out a list of all diseased places in his district; to report all dirty places; to visit and inspect all his district, and report the same; to visit from house to house and administer medicine in all cases of diarrhoea, or choleraic disease; and numberless other duties; and all gratuitous. But neither in the whole range of the officials created by the lunacy acts, or the sanitary acts, are there any who are not paid for their services, save her Majesty's Secretaries of State, and the Poor-law medical officers.

The heads of our profession, by the eagerness with which they seek after gratuitous appointments, bring down on those of their brethren, who have to struggle hard for their daily bread, injuries unspeakable. And it is in vain to seek relief from public boards or private bodies, so long as the present blighting customs remain unreformed.

I am, etc.,

A COUNTRY SURGEON.

October 1st, 1853.

ADVICE GRATIS IN PURE AND IN GENERAL PRACTICE.

LETTER TO THE EDITOR.

SIR,—I am fully prepared to acknowledge with you the injustice done to the general practitioner, by the wholesale gratuitous advice system; on the other hand, I cannot shut my eyes to the glaring injustice done to the public by the apothecary who vends his drugs, and whose account is swelled by the amount of physic supplied, which, alas! in too many cases, is prodigious.

Often am I applied to for gratuitous advice, in cases which had they been dieted and judiciously managed, instead of being drenched by the stuff of some apothecary, would have speedily recovered their maladies. Can I, sir, in justice and humanity, refuse my services to such as those who, mulcted of their means and time, implore my aid in despair!

I am no homœopathist; I abominate the delusion and its professors; still so glaring are the evils of the apothecary system, which would be tolerated in no other country than Great Britain, that I would rather be duped by the former than drenched by the latter.

I, for one, shall stoutly resist any interference with the gratuitous advice of the "pure", so long as these glaring evils in the apothecary system are countenanced; to the practitioner of which, I would say: "Thou hypocrite, first cast out the beam out of thine own eye, and then shalt thou see clearly to cast out the mote out of thy brother's eye."

I am, etc.,

JUSTICE.

October 29th, 1853.

FALSE POSITION OF THE MEDICAL PROFESSION.

LETTER TO THE EDITOR.

SIR,—Surely, there never has been a time when the medical profession was more loudly called upon to exert itself to defend and support its own dignity than the present. What with negligence and lukewarmness, and a want of unanimity on the one hand, and a grasping overburthening disposition on the other, we shall ere long deserve the scorn with which we are threatened, if we do not rouse ourselves to repel it. Without attempting to decry others, let us compare the respective positions and prospects of our own profession with those around us. In every other profession there is something to look forward at; some office or station of high rank, honour, and emolument. In the army and navy there are captains, colonels, admirals, generals, peerages, and pensions. The church has its good livings, its canonries, its deaneries, its bishoprics, and archbishoprics. The law has a field for wealth, patronage, and honour, large enough to satisfy the cravings of a cormorant: its offices are innumerable, and its emoluments such, as make a poor medical practitioner's mouth water. There is no office in the state to which he may not aspire; from a town clerk or revising barrister up to a lord chancellorship, or a privy councillor—peerages included. The House of Commons abounds with them; and, for the most part, fortune smiles on them.

What object of ambition is there for a medical man? With an education second to none of any other profession, there is not one single office of high rank, honour, or profit, to which he may aspire, unless he belongs to the army or navy. Look at the medical officer of a poor law union, with a territory of ten, fifteen, twenty miles diameter, to attend to, and a salary that will hardly pay for his horse's shoes. There are medical officers of hospitals, dispensaries, and infirmaries, no doubt; but, for the most part, without a shilling of salary, whilst the labour and responsibility is very considerable. No doubt, it is a very honourable office. So it is to be a bishop or a judge, a canon of a cathedral or a solicitor general; but I doubt if there would be many candidates for these honourable offices if there were no stipend or salary attached.

I have spoken of a medical man's education: let us glance for a moment at what it is. He has passed through the usual routine of school and collegiate instruction, and being grounded in English, Latin, and Greek, French, Italian, and German; he is expected to have a fair knowledge of geography, astronomy, mathematics, and algebra; as well as the principles of optics, acoustics, mechanics, hydrostatics, pneumatics, meteorology, and the causes of the variation of climate, etc. He then proceeds to the subjects more decidedly appertaining to his profession; viz., anatomy, human and comparative, general and microscopic, physiology, pathology, surgery, midwifery, medical jurisprudence, botany, mineralogy, and the *materia medica*, the practice of physic, and chemistry, with its concomitants, electricity, galvanism, magnetism, and the phenomena of light and heat. A medical man in society is expected to understand something of every science and art; and people often judge of his acquirements in his profession by the amount of knowledge he may possess on general scientific subjects. This is natural, and we do not complain of it. On the contrary; the more enlightened a medical man's mind may be, the higher is the range of his intellect, the greater will be his general utility and skill, and the greater will be his own gratification. But this is a gratification entirely his own, earned by the sweat of his brow, by study and mental exertion, and stands in no degree in the place of pecuniary reward. I will venture to say, that the medical profession, as a body, may rank amongst men of the highest and most cultivated intellects in the kingdom; of a refinement of mind, of learning and acquirements, and clearness of perception, that would do honour to any rank or any station.*

These are the persons who are called out at all hours and in all weathers to listen to the disgusting details of every ailment that the dispensations of Providence, or the folly or wickedness of mankind, can produce; to forbear with the peevish, to calm the excited, to face and outface the maniac at the risk of his life sometimes; to have patience with the fanciful, to convince the wrongheaded and obstinate; to be thwarted by stupidity, obstinacy, prejudice, and parsimony; to be treated with ingratitude and neglect when the emergency is past,—yet bear it all with

patience and resignation. A medical man's time is part of his stock in trade, yet some will hold him by the half hour putting cases and trying to get clandestine opinions from him without offering a fee; others will inflict long correspondences on him requiring answers backwards and forwards, frequently on matters in which a lawyer would be the better adviser, only, he would demand his fees each time, but the doctor of course is not expected to charge. And this feeling is become so much a matter of course, that the legislature now think themselves justified in demanding our services without remuneration. We have but just opened the eyes of the insurance offices on this subject, and now the government comes down upon us with this compulsory registration Vaccination Bill. It is in every way so unreasonable in its demands, and so inconvenient in its working out, that it must ere long fall to pieces of its own weight, but we must not aid in building it up. What do we receive either in honour or profit, what do we get out of the coffers of the state, or any other public source, that should induce us to add one tittle, one feather's weight, to the burthen we already bear? On the contrary, do they not exact the uttermost farthing out of our precarious incomes in their income tax? Why then should we be called upon to give gratuitous certificates, or take any additional trouble, without remuneration? I mention these subjects for the purpose of urging upon the profession the necessity for a unanimous and concentrated effort to procure a speedy and thorough medical reform. There is much to be said on the subject; but I have already so far trespassed on your space, that I will only add, that I believe our profession is at present the hardest worked, the worst paid, the least thanked, and the most abused of all the professions.

I am, etc.,

E. X. O. N.

November 5th, 1853.

NEWS AND TOPICS OF THE DAY.

LONDON UNIVERSITY GRADUATES. A numerous attended meeting of the Graduates' Committee of the University of London, was held at the Committee Rooms, on Tuesday evening, Nov. 29th, to consider what course should be adopted with reference to the intolerant proceedings of the members of the College of Physicians, in black-balling Dr. Ransom at the Royal Medical and Chirurgical Society. Dr. Ransom was unanimously elected a corresponding member of the Committee; and we understand that immediate steps will be taken to bring the question of the alleged illegality of the degrees of the University of London before Government, and to take such other steps as will ensure the Provincial Graduates and Physicians from a repetition of further insult from the College of Physicians.

A NEW PERIODICAL:—THE ASYLUM JOURNAL. A periodical under this name, and edited by Dr. Bucknill, has been established by "The Association of Medical officers of Asylums and Hospitals for the Insane." The association found that they were powerless without a special organ of their own, so great was the difficulty of obtaining an adequate attendance at meetings. The editor in his introductory address remarks:—"When the members of an association cannot meet, if no attempt is made to substitute the power of the printing press for that of the assembly, such an association cannot even claim an existence of decrepitude: it must be in a state of complete and absolute palsy." We are told that at the meeting at which the Asylum Association resolved to have a journal of their own, "Dr. Conolly added the weight of his great authority, and spoke with much emphasis of the treasures hitherto hidden in Asylum case-books, likely to become known and useful to mankind through the intervention of such a journal." The *Asylum Journal* contains sixteen pages of matter: and is to be published in the meantime only once in six weeks. It is evidently not intended as a substitute for, or as a rival of Dr. Winslow's Review, but rather as a medium of communication and publication for members of an important society.

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

- *COOPER, Henry, M.D., elected Mayor of Hull for the ensuing year.
- *DUNCAN, J. Matthews, M.D., appointed Physician Accoucheur to the Royal Dispensary, Edinburgh.
- WINN, James M., M.D., elected Physician to the Metropolitan Dispensary.

* I say this, notwithstanding it pleases Mr. Charles Dickens and his brother scribes to introduce us, most commonly, in some ludicrous light into their stories—no great compliment to their own professional attendants, whenever they may be.

MEDICO-METEOROLOGICAL OBSERVATIONS

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XLIX.

LONDON: FRIDAY EVENING, DECEMBER 9, 1853.

NEW SERIES.

MEDICAL STUDENTS.

No one can help being conscious that the position of medical students, from the time they leave the homes of their parents, or of those with whom they have spent the earliest years of their pupilage, has not sufficiently attracted the notice of the profession. The aching heart of many an anxious father can bear witness to the feelings with which the son is first dismissed to his studies in London, or some provincial town. The consciousness that there is no one to take a parent's place, nor to aid in guiding the aspirant for medical honours amidst the dangerous temptations to idleness and vicious pleasures which surround him, adds a bitter pang to the farewell. Every public teacher can bear witness to the number of letters of anxious introduction he receives on the opening of each medical session, from the parents and masters of the new pupils; and how gratefully the promise to extend some friendly care to the student is received.

That there is something radically wrong in the plan of education pursued during the student's hospital studies, is sufficiently obvious from the statistics of Mr. GUTHRIE, to which Mr. PATERSON has directed attention in this number of the ASSOCIATION JOURNAL. The fact that, out of 3,290 registered students, only 1,250 obtained the diploma of the Royal College of Surgeons, is really startling; and that, on an average of three different medical years, one in nine was rejected, is as painful. Here is indeed a subject meriting the most serious attention of our profession generally, but especially of those who are devoting themselves to the education of the rising generation of medical men.

Our correspondent expresses his opinion that "the students are more idle and inefficient than ever". Earnestly do we hope that this is a partial statement. It is certainly opposed to the testimony of Dr. GOLDING BIRD, in his recent letter to the Journal (p. 1042); and his sphere of experience has been ample, although limited, we believe, to Guy's Hospital. When we look at the satisfactory results of the preliminary classical and mathematical examination, to which the Apothecaries' Company has, within the last few years, invited the students at the commencement of their career, no less than to the manner in which so many have passed through the difficult ordeal of the University of London, and have distinguished themselves by obtaining its medals and scholarships, we cannot but hope that there are very many splendid exceptions to the character given by Mr. Paterson to the present generation of medical students.

The more general adoption of the tutorial system in our hospitals and schools would be an unquestionable boon to the students, and as great a benefit to the large number of young physicians and surgeons who remain in attendance at these institutions after the completion of their routine education; and many of whom, with great talents and small means, spend years in the long deferred hope of some over-worked senior making way for them. This indeed leads us

to repeat a question which has been more than once proposed, namely—Whether the tenure of office in a medical school or hospital should continue, as is too often the case, after increasing years or accumulating practice have rendered it impossible for the teacher to devote sufficient time to those who look to him for instruction?

To pass from the professional to the moral and religious training of the students of medicine—It is difficult to overrate the importance of any scheme which may be successful in reminding the student of his responsibilities. The adage of *Nulla religio, nulla fides*, is as true as it is old; and never will medical men perform their mission so usefully and happily as when their talents are purified by Christian love. Then indeed will they learn practically to bear and forbear with each other, and with their patients; and the bickerings and misunderstandings, which now so often unnecessarily strew thorns in the anxious path of a medical career, will lose their power to wound under that influence which teaches them to bear one another's weakness.

A study of the biographies of some of the real benefactors of our profession, of Harvey, Sydenham, Boerhaave, William Hey, Bateman, Jenner, Good, Gooch, Hope, Turner, Abercrombie, John Reid, and of many more, will show that, brilliant as were their scientific attainments, they were rendered still more illustrious by the Christianity they openly confessed. Indeed, to borrow the words of a former correspondent (p. 657), we feel assured that the fearful stigma, *Ubi tres medici duo athei*, is not merited by our profession; and "that the time has gone past when medical men shall hesitate to mix up with their God-like profession a Christian confession."

We feel sure that any attempt to preserve and extend moral and religious influences among students, during their residence at the hospitals and schools, cannot fail to receive the warmest approbation and the most earnest support of our profession. Those who endeavour to carry out these views, may at least count upon the assistance of nearly all who are desirous for the elevation of the status of the medical man, and for the protection of the student against those vicious temptations on which his health, his happiness, and his usefulness are too frequently wrecked.

In conclusion, we would remark that the letters which have been elicited by the appeal published on the 11th of November (p. 1002), sufficiently show the warm interest which is taken in the cause of medical students: and the announcement by Sir CHARLES HASTINGS in this day's number, is evidence that our ASSOCIATION has already recognised the claims upon its sympathy of the rising generation of practitioners.

THE VACCINATION QUESTION AND ITS SETTLEMENT.

THE letters which we publish to-day, and others which have appeared in the ASSOCIATION JOURNAL since the passing of the New Vaccination Act, clearly indicate that

it is beginning to produce the fruits which we predicted—contention and complaint. If the former act was largely productive of these evils, it was natural to suppose that the present “compulsory” act would yield them in still greater abundance. The history of this and other measures shows how difficult it is to protect the profession from adverse legislation, and from the sectional policy and ill directed zeal of its own members. The medical profession, it is admitted, is step by step sinking under the yoke of the Poor Law Boards: and no one tries to stop the descent. This state of matters is apparently both the cause and the effect of apathy; for we can in no other way explain the indifference which prevailed regarding the Lunacy and Vaccination Acts when they were before Parliament last session.

We do not think that any good can result from a reiteration in these pages of opinions regarding Lord Lyttelton's Act. If any satisfactory settlement of the vaccination question can be arrived at, we believe it will be through the agency of a representative Committee of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION, appointed after discussion in all the Branches.* The Association loses much, in fact nearly all, its political power, by its want of a representative organisation; and, till we adopt and cherish such an organisation, we shall probably continue, as at present, to waste our energies upon useless and ill sustained sallies. Our troops are numerous; but they have yet to learn the tactics of combined operations.

MILITIA SURGEONS.

THE grievances of the Militia Surgeons have been actively taken up by a Committee of their number, who are now seeking the concurrence of their constituents to convene an early meeting at Birmingham. Communications to the Committee may be addressed to Dr. W. WILLIAMS, Royal Flint Rifles, Mold, North Wales. We hope that the profession generally will support the cause of the militia surgeons, as it is the cause of justice and fair play. The subject is sufficiently explained by the letters in this and a previous number of the ASSOCIATION JOURNAL, so that we need not say more regarding it at present.

INDECENT EXHIBITIONS.

IN the newspapers we have often read Dr. Kahn's invitations to ladies to visit his museum on Fridays, at certain hours, when, as the advertisements state, the other sex is excluded. For example, in the *Critic* of 1st December, we observed the following:—

“Wednesdays and Fridays, from 2 till 5 o'clock, a part of Dr. Kahn's Anatomical Museum is open for ladies only, when lectures will be delivered by Mrs. Leach. On those days, gentlemen will still be admitted from 11 till 2, and from 7 till 10; while on other days, the museum will be open for gentlemen only from 11 till 5, and from 7 till 10. Lectures by Dr. Leach. Admission, One Shilling. Portland Gallery, Regent Street, opposite the Polytechnic.”

From this notice, it was obvious that ladies were publicly invited to view objects, which they could not have the face to look at in the presence of men; but till we received the letter from Mr. Kesteven, which we have published in a subsequent page, we had no idea that this arrangement was so much necessitated by the grossly inde-

cent character of the exhibition. The wax models of Dr. Kahn are very beautifully executed; and in a collection destined for medical students or others engaged in scientific pursuits, most of them might be exceedingly appropriate; but as mere sights for the general public, many of them can only be called filthy—and, as spectacles for women, outrageously abominable.

In the portions avowedly open to females, we find in the catalogue the following and such like entries:—

- “64. Sexual organs of a young female in a state of virginity showing the hymen.”
- “67. A testicle and epididymis injected with mercury.”
- “95. The penis laid open, showing its structure.”

In the “room for medical gentlemen”, the objects are precisely such as would not attract them—and for them the descriptions are neither necessary nor intended. To admit women to this reserved collection upon payment of an extra shilling is very nasty. That our readers may form their own opinions on this point, we copy a page from Dr. Kahn's catalogue—the very catalogue which all visitors, male and female, are invited to purchase:—

“641. The internal sexual parts of the European female in a state of virginity:—*a*, the external labia, or lips; *b*, internal labia, and at their point of junction is a little conical gland, called *c*, clitoris; *d*, the entrance to the bladder; *e*, the entrance to the vagina, which in virginity is partially closed by a membrane, called *f*, hymen, or virginal membrane; whose absence, however, is not by any means a proof of unchastity, as it is sometimes deficient from infancy, and at other times is so slight as to be ruptured by ordinary exertion.

“642. The external female sexual organs, in a state of virginity.

“643. Sexual parts of a Lapland woman, showing the hymen.

“644. Sexual parts of a Hottentot woman, showing an enormous enlargement of the inner labia, through which a ring has been passed for the purpose of preserving chastity.

“645. A Hottentot woman, with pendulous clitoris or natural apron.

“646. A Hottentot woman, with an enormous clitoris. It is said that women of that race purposely elongate the clitoris themselves, and mutually satisfy their sexual propensities.

“647. By this is represented an elongated clitoris, seen in a girl, still living in Munich, and who since the age of eight years has practised Onanism (or self abuse) to such an extent, that the clitoris has become enlarged.

“648. Enormous enlargement of the prepuce of the clitoris, in an English female, also arising from Onanism.

“649. Elephantiasis of the female sexual parts. In this figure is also seen the result of Onanism.

“650. Elongation of the testicle, caused by Onanism.

“651. Head and face of a man who fell a victim to the demoralising and destructive habit of Onanism.

“652. Spinal cord diseased by the effects of onanism, taken from a boy twelve years of age, who died in the hospital in Vienna.

“653. Sexual parts of an individual, who is still living in Paris: the scrotum is split, the penis like the clitoris of a woman, joined to the scrotum without being pierced, the evacuation of the urine is by an opening resembling a vagina, which is seen beneath the sexual parts.

“654. Sexual parts of an individual named Gottlich, born near Dresden, in Saxony; his scrotum consists of two equal parts; instead of the penis there is a species of clitoris, beneath which is found an opening two inches deep, by which the urine is evacuated.

“666. Purulent discharge from the urethra, called gonorrhœa, with curvature of the penis, known by the name of chordee.”

In “the opinions of the press”, appended to the catalogue, we find the following from the *Observer* of June 15th:—

“Almost every officer of the Life Guards and Blues, with many of the non-commissioned officers of those fine regiments, have examined minutely the wondrous structure of the human

* It will be seen (p. 1089) that the Vaccination Act is to be taken into consideration by the Metropolitan Counties Branch, on the 13th instant.

frame, there so elaborately and faithfully developed. During the last week, upwards of two thousand visitors have honoured the museum with their presence; amongst others Lords Loughborough, Seaham, and Adolphus Vane, Sir George Wombwell, Colonel Lygon, and many others of the *haut ton*."

No names of fashionable ladies are given; whence we may infer that the male *haut ton* above mentioned are fully as inquisitive, if not more so, than those whom Mr. Kesteven designates as "the most inquisitive of mortals".

GOLDEN OPINIONS.

In our impression of November 25th we gave some little peeps behind the scenes, as a foretaste of fuller disclosures regarding commercial and professional advertising. We showed that editorial praises were often literally *golden opinions*, and that they differed only from common advertisements in the style of their typography and their locality in the paper. The bribe offered by Du Barry and Co. to the *Reformers' Gazette* having formed the text of our remarks, we now communicate the correspondence which has appeared subsequent to our report of the exposure of that transaction. The false charges and mock morality of the convicted parties are good examples of the weapons with which unscrupulous persons of their class attempt to defend themselves from the shafts of honest editors. Such persons always seek to retire behind actual or threatened slander. Unfortunately, this policy of impudent intimidation silences many a timid foe, as the history of the venal press too abundantly proves.

The fear of being slandered in the *Satirist*, we have heard, brought much wealth to its nefarious proprietors, till at last some bolder than the majority of fashionable men refused to dole out *black mail*, and, regardless of the dirt and filth of the fray, battled with those whose trade was to invent calumnies that they might get a bribe for their suppression. The same description of contest must always be waged when there is a similar enemy to war with. The champions of truth must glory in the imputation of vileness, and reckon detraction as the best tribute to the success of their labours. They must remember that, as far as they are concerned,

This is no world
To play with mamnets, and to tilt with lips:
We must have bloody noses, and cracked crowns,
And pass them current too.

The editor of the *Reformers' Gazette* spurned Du Barry's bribe, and exposed the insulting offer. We naturally praised the *Gazette*—and as naturally Du Barry bullied and slandered it; thus illustrating the proposition we have above enunciated.

Smarting under the exposure of the bribe, the pease meal gentlemen addressed the following letter to PETER MACKENZIE, Esq., the editor of the *Reformers' Gazette*.

"London, Nov. 21st, 1853.

"Editor of Glasgow Reformers' Gazette, Glasgow."

"SIR,—There is a species of bad faith or dishonesty, which it is universally understood that you are acquainted with, and which the text of our advertising order sent you on the 10th November, was intended to protect us against. It consists in an editor or proprietor—after having received the money from London advertisers for insertions in all editions—inserting the announcements in a few copies only, which he calls his first edition, and of which one copy is sent to the London advertiser, to prove the execution of a dearly paid for contract; whilst the advertisement is carefully removed from the main issue of the paper, and which then is called the second edition!

"Persons acting thus dishonestly, are always annoyed when found out.

"We should have taken no notice of your attack upon us in

your second edition of 19th November, had it not been for the deliberate falsehood you therein publish, as to the composition or nature of our food; and which we hereby formally contradict.

"We should fancy that the honest people of Scotland, before they adopt you as their reformer, ought to insist upon your first reforming your own principles for truthfulness and morality, for they certainly require a thorough reform.

"Your wallwishers for amendment,

"BARRY, DU BARRY, AND CO."

Mr. Mackenzie returned the following reply, which, along with the above, he has published in his paper of Saturday, the 3rd December.

"Gazette Office, Glasgow, Nov. 24th, 1853.

"To Du Barry and Co.

"SIRS,—Your audacity is only equalled by your knavery.

"The reply we make to your impudent letter just received is, that we neither touched your money, nor entered into any contract whatever with you, either for our first, second, or third edition, or for any edition whatever. On the contrary, for the last three years, we have invariably declared that we would not admit your advertisements into our columns 'on any terms'. When, therefore, you had the insolence to attempt to bribe us (as to the shame and disgrace of the press you have evidently too often done in other quarters), by sending such orders, and getting such concocted, fraudulent puffs inserted week after week *ad nauseam*, we thought we took the best course with you by simply publishing your own impudent proposals.

"As for our *truthfulness* and *morality*: the first of these inestimable qualities will, we hope, be directed to open the eyes of the public still farther to the fraud and knavery practised upon them by quack impostors now so largely abounding; and as for our *morality*, we have the great satisfaction to know that no part of our character depends for support either on quack vagabonds, or audacious impostors.

"We remain your uncorruptible foes, but sincere wellwishers for amendment and honesty,

"PETER MACKENZIE."

As a sequel to the peep behind the scenes which Mr. Mackenzie has afforded us, it would be both curious and instructive to have a list of all the newspapers in which *quasi* editorial praises of the *Revalenta Arabica* have appeared. Such a harvest of golden opinions would form a tolerable gauge of the immorality of the press, and point out at a glance the names of those papers which are venal.

ORIGINAL COMMUNICATIONS.

REMARKS ON CHRONIC INFLAMMATION.

By C. HANDFIELD JONES, M.B.Cantab., F.R.S., Assistant Physician to St. Mary's Hospital.

It seems worth while to try if any correct discrimination can be made among the various morbid phenomena, which are commonly regarded as the results of chronic inflammation. It is scarcely too much to affirm that this name is a kind of refuge, to which we betake ourselves when we have very little certain knowledge of the causative conditions of a morbid change. Cirrhosis of the liver we suppose to be chronic inflammation of that organ; morbus Brightii is sub-acute or chronic desquamative nephritis; white pericardial patches indicate pericarditis; enormous fibroid thickenings of the coats of the stomach are set down to chronic gastritis; and various chronic changes in the valves of the heart, the cerebral tissue, and bone, are often regarded as produced by the same cause.

To say simply that such or such a change is due to chronic inflammation, means, in strict language, no more than that a process the same as acute inflammation in kind, but of much slower course, has given rise to it. So at least it is defined by our best English authorities. Dr. Williams says, that an inflammation lasting above three weeks is sub-acute, and, if protracted beyond six weeks, is properly called chronic." Dr. Watson asks, "Is acute inflammation

different from chronic in *kind*? No, they differ only", he replies, "in degree. . . . The process is the same, but its features are less strongly expressed. The disease passes through similar stages in both cases, but it travels at a different pace." Dr. Alison speaks in the same terms, but adds an important reservation. He says, "The term chronic is properly applied to those inflammations which tend to the same consequences, and, in many instances, infer the same danger as the acute, but run their course much more slowly, and generally with less urgent symptoms." After remarking, that the sequelæ of acute may be put down as examples of chronic inflammation, he proceeds, "It is proper also to exclude, at present, from chronic inflammations cases where adventitious textures are formed, distinct from the ordinary products of inflammation, although there be much difficulty in distinguishing these forms of disease by their symptoms." Rokitsky extends more widely the demesne of chronic inflammation; he distinguishes four kinds—(1) that in which the process tarries long in each of its stages, even that of congestion taking place very gradually; (2) that in which the inflammation consists in protracted congestion, with retardation of the blood current inclining towards actual stasis; (3) chronic inflammation made up of successive complete attacks of more or less acute character; (4) inflammations producing pus or sanies from internal or external causes, so markedly chronic that they are like a process of secretion. Mr. Paget scarcely mentions chronic inflammation: the only remark I find is, that the acute or chronic character of the process determines the degree in which "the product deviates more or less from the character of the natural effusion or blastematous effusion in the part." Andral, as is well known, rejects the term inflammation altogether, and regards merely varieties of hyperæmia, active, passive, or mechanical. He thinks chronic hyperæmia may be sthenic or asthenic, active or passive. Mr. Wharton Jones, in his *Essay*, does not touch on chronic inflammation.

I am not so presumptuous as to think that I shall completely explain, or even much elucidate, the obscure form of a process itself obscure; but yet I believe I can, by the following observations, somewhat more clearly define the limits which ought to be assigned to it. Acute inflammation occurring as the result of injury in a healthy person is a *typical case*, certainly not that most commonly met with. The main features of this are, (1) hyperæmic afflux; (2) partial and local stasis of blood in the capillaries; (3) impairment or complete arrest of the nutritive actions of the part; (4) exudation of plasma in excess, the more so as the part is unable to use its ordinary proportion. In the typical case, the inflammatory process runs a tolerably definite course, and naturally tends after a time to decline and cease; the exudation being either absorbed, or converted into induration matter, or changed into pus. Now, from this typical condition, most if not all the instances of what is called chronic inflammation depart, in other respects than in being of slower course. Many of them, such as chronic conjunctivitis and bronchitis, are nothing but congestions of atonic vessels, with increased secretion of the mucous membrane: there is no hyperæmic afflux. In others, such as various skin diseases, syphilitic eruptions, and rheumatic inflammations, there is a continual or oft repeated irritation kept up by the determination of a *materies morbi* to the part affected: the exciting cause does not cease to act. In other cases, fluxes from mucous surfaces take place, or perhaps serous effusions, which may have been initiated by inflammation, but remain as secondary results of that process, which has itself ceased. In others, again, the exudation, which takes place interstitially, organises itself into tissue of a low form, and gives rise to the so called unreal hypertrophies. Now, it does seem to me that, in this last instance, a new and most important feature has appeared, one which is absolutely foreign to the typical case of acute sthenic inflammation. In that, the exudation is either wholly reabsorbed, or it is thrown off as pus, or it is partially reabsorbed, and partially remained as a block of induration. In the latter

case, it shows no tendency to grow, to hypertrophy; but, on the contrary, to waste and shrink. We have seen layers of effused lymph on the pleura in course of becoming areolated, and vacuolæ forming in them by absorption, like the holes in the fenestrated membrane; and so the originally solid mass becomes converted into the delicate translucent bands of adhesion with which we are so familiar. Or take the results of inflammatory effusion in other parts. We all know how great is the tendency of organised fibrin to contract and draw together, as seen in the deformities produced by burns, the indentations of even the dense substance of the liver over fibroid cicatrices, and in puckerings of the surface of the lungs from a similar cause. I desire to dwell on the circumstance, that the simple inflammatory exudation does not enlarge itself, and grow, and encroach on the surrounding tissue, but contracts and shrinks together till it becomes, if possible, a mere linear streak. Decidedly, its tendency is to diminish in size.

But let us now take a case of cirrhosis of the liver, such as are not unfrequently met with when the bulk of the organ is not materially diminished. How strikingly *different* is the condition here! On the surface of a section, we may find considerable tracts of fibroid tissue running in among the lobules of the parenchyma, and grouping them together in irregular masses. The quantity of fibroid tissue may equal that of the remaining parenchyma, as in a case I lately examined; or even, as Rokitsky states, may preponderate over it. Microscopic examination shows the fibroid tissue to consist of a kind of fibrifying blastema, imbedding multitudes of nuclei, round or elongated. Now, it is clear that, in this case, there is a growth and development of tissue quite altogether unlike anything that takes place in acute inflammation, or even in such chronic inflammations as those of skin diseases and rheumatism. In fact, the evidences of inflammation are exceedingly questionable, and, so far as hyperæmia is one, are almost wanting. Neither have we any evidences of stasis occurring, and we know that the nutritive actions of the part are not suspended. All that we certainly know is, that exudation takes place, and is organised, in a way that it ought not. Now, I do very strongly demur to calling a change of this kind by the name of chronic inflammation, if the definitions of Dr. Williams and Dr. Watson are to hold good. Neither does the more extended one of Rokitsky at all fairly include it. I would put it to any one, whether there be not much more real resemblance between such a case of fibrous production in the liver as I have described, and the formation of a fibrous tumour in the uterus, than between the former and the result of any unequivocal inflammation. In the fibroid thickening of the walls of the stomach, which may be such as to make them stiff and resistant, it is well remarked by Andral, that the only difference between this state and that of a fibrous tumour is, that the areolar tunic has thickened itself in the one case as *ten locally*, in the other as *two over* a greater extent. Generally, I believe that, in the following instances, viz., cerebral hypertrophy, chronic simple enlargement of lymphatic glands and of the tonsils, Corrigan's cirrhosis of the lungs, the Pacchionian glands, patchy and nodular thickenings of serous membranes, as often seen in the capsule of the spleen, and in thickening and contraction of the cardiac valves taking place without apparent symptoms of endocarditis, the process is not to be regarded as a chronic inflammation, but as an hypertrophy, or new formation, with which there may coexist some, generally a very slight, amount of hyperæmia.

I have said, that acute sthenic inflammation occurring in a healthy person was the type of inflammation; but I am quite aware that it is impossible to draw an exact boundary line between this and the developmental processes that give rise to new products. The types are far apart, but the space between is filled up with innumerable instances of transition from one to the other, in which the distinctive characters become variously blended. This has been recognised and well illustrated by Mr. Humphry, in his *Lectures on Surgery*, published in the *Provincial Medical and Surgical Journal*. He says: "This compartment

of pathology, intervening between inflammation and hypertrophy, to which the term inflammatory hypertrophy may be given, embraces a large number of morbid products which have hitherto remained unclassified, or which have been arranged in such a manner as to convey no idea of their real nature." He distinguishes three classes of cases, in the first of which inflammation lingers on a long time without causing any structural change; in the second, it lingers on in the same way, but is attended with hypertrophy; and in the third, it subsides, after having given a stimulus to the hypertrophy, which then goes on without it. It seems to me in the highest degree probable, that in many of those cases which Mr. Humphry would comprise under inflammatory hypertrophy, there is no true inflammation, but one only of its parts, viz. more or less of hyperæmic afflux. The instance of elephantiasis to which he alludes, seems, from all that we know of its pathology, to be certainly widely different in its real essence from any mere inflammation either of the lymphatics or of the skin. Whatever inflammation may have to do with it, there is, certainly, some other cause infinitely more potent. Were it not so, why should not a severe case of psoriasis, or repeated attacks of rheumatism or gout, or the irritation of diseased bone, or deep-seated cellular inflammation, cause similar hypertrophy? These hyperæmic causes do not produce this effect, because with them there does not coexist that peculiar alteration of the normal qualities of the plasma and the tissue necessary to healthy nutrition, which is the chief factor in the process giving rise to elephantiasis. I would wish to name all these morbid changes in which the character of growth—of new formation—decidedly predominates over that of inflammation, according to their principal feature. I would call them simply fibroid thickenings, or fibro-cellular growths, and thus avoid giving them a name, either merely trivial, or of doubtful correctness. The matter is not one of nomenclature merely; it has important bearings on practice. Suppose a case intrusted to our care in which the liver was found considerably enlarged, projecting below the ribs, and that we have satisfied ourselves that the enlargement depends neither on engorgement with blood, nor on fatty change, nor on bacony deposit. The probability, then, is very strong that it is in a condition of cirrhosis, the fibrous tissue between the lobules being prodigiously increased in quantity. Can we hope by the administration of mercury or iodine to remove this deposit? If it were simply inflammatory, the attempt might be successful; but as it is a growth, one may confidently predict that it would be fruitless if not injurious. The same remark will apply more or less completely to any of the other instances before mentioned.

It seems to me that observers have not sufficiently held in view, although generally admitting as a matter of course, the vast predominance of that unknown force, call it what we please, which determined and still determines that here bone and there muscle, and in another spot nerve, and in another tendon, should be formed. There is some such force, and it is certainly liable to be deranged, and its derangements are just those which are most difficult to rectify. This perversion of the nutritive act (to borrow Andral's phrase) is that which determines the origin and growth of a cancerous, or a fibrous, or any other kind, even of a fatty tumour. It is the same, I believe, which causes the textural changes above enumerated, and some others which might be added, and not inflammation, which of itself and in its best marked form, produces no exudation which is capable of growing and enlarging. It is this property of vegetative increase which makes the removal of new formations and all allied productions so difficult: mere inflammatory effusions we can melt down and get absorbed, but these resist our "sorbefacient" remedies with the same persistence almost as the natural tissues.

The degenerative process which constitutes true morbus Brightii does not quite come under the above class of morbid changes. The best observers are agreed that production of new interstitial tissue constitutes no essential part of the morbid action. Most writers incline to view it as a nephritis

of more or less chronic character; but the great name of Prout can be cited in support of the view that the substratum of the process is something essentially different from inflammation. My own observation has always inclined me to adhere to this opinion. In the enlarged, often mottled, kidney we see simply a derangement of nutrition, producing hypertrophy of the epithelium concurrently with malperformance of its function. The albuminoid cell-growth does not undergo its normal changes; and instead of forming the secretion, it collects in the tubes, either choking them up and distending them, or getting washed out in the stream from the Malpighian tufts. In further stages, or in more rapid degrees, of change, the tubes and epithelium break up into mere detritus. In all this process we see really nothing to justify us in considering it as inflammation. So, also, in the atrophic form, the small dwindled kidney, we find no satisfactory evidence of anything else than a gradually supervening impairment of the nutritive process. The epithelium wastes, and the tissue decays, and collapses; thus far is certain; but how little is there to show that this is dependent on previous inflammatory disease? On the contrary, the frequency of recovery from acute congestion (as that of scarlatinal dropsy) shows that inflammatory and degenerative actions are widely different in their nature and results. The one exhibits the perturbation of healthy action by an intervening cause, the other is the decay of vital power from innate or induced weakness.

The subjoined scheme illustrates the transitions that seem to exist between two of the chief types of disordered nutritive action. In inflammation of acute sthenic character the hyperæmia is a main element, and the exudation is non-vegetative. In cancer (say encephaloid) there is no apparent or necessary hyperæmia, but the exudation is endowed with a vegetative power of most active growth. In simple deposit, as of tubercle or bacony matter, there is neither hyperæmia nor manifestation of vegetative power; the sole morbid change is the deteriorated state of the plasma.

Inflammation.

Acute sthenic.
Subacute.
Chronic.

Tubercle—bacony matter.
Simple deposit.

Encephaloid cancer.
Fibrous tumour.
Fibroid thickening.

Southwick Place, Hyde Park, November, 1853.

AN EXPERIMENTAL INQUIRY INTO THE EFFECTS OF INJECTING PUS INTO THE VEINS OF ANIMALS.

By JOSEPH SAMPSON GAMGEE, Esq.

EXPERIMENT I. Oct. 17th, 1853, 10 A.M. The subject was a perfectly healthy horse; pulse 33; the respiration 10 in a minute. The left jugular vein was opened, and a mixture of two and a half drachms of good pus, with the same quantity of tepid water, were injected into it slowly, and without the animal being in the least disturbed. It was ascertained that the vein continued quite pervious some moments afterwards, by its filling upon pressing on it just in front of the sternum.

12 meridian. No change had hitherto taken place, but the animal had now begun to breathe twenty-five times per minute. The pulse was 42, of good character.

4 P.M. Pulse 60; respiration 30, thoracic.

8½ P.M. Pulse 64; respiration 24. The horse fed well, and appeared in good health.

Oct. 18th, 7½ P.M. The animal fed, and was lively. The respirations were 20, and much less thoracic than last evening. Pulse 68, full, and oppressed. The vein was pervious.

2½ P.M. Pulse 54; respiration 20.

7½ P.M. Pulse 64; respiration 24.

EXPERIMENT II, instituted on the same animal on October 19th. 10 A.M. The pulse was 51, of good character; the respirations were 20, not manifestly thoracic.

10½ A.M. An opening was made into the right jugular

vein, and a mixture of two drachms and a scruple of pus, with an equal quantity of water, was injected into it. A good deal of difficulty was experienced in endeavouring to pass the nozzle of the instrument into the vein; and I infer from the following facts, that, after all, the fluid was only injected into the subcutaneous cellular tissue:—1stly. A swelling immediately appeared below the orifice; 2ndly. The vein distinctly filled above when pressed upon below, which it could not have done if the swelling had been due to its obliteration; 3rdly. The animal, ten minutes after the injection, was not in the least affected by it.

7½ P.M. Pulse 54; respirations 20.

Oct. 20th, 2¼ P.M. Pulse 96; respirations 20. Both jugular veins were pervious. The swelling on the right side of the neck was diffused and sore. A thrombus had formed on the left side, and pus escaped from the orifice.

EXPERIMENT III, performed on an aged grey horse, affected with extensive melanosis of the tail and anus, but otherwise perfectly healthy. Pulse 38.

Oct. 24th, 12 merid. A mixture of two drachms and a scruple of good pus, diluted with an equal quantity of tepid water, was injected into the right jugular vein. I had no sooner done this, and transfixed the lips of the orifice with a pin, than the horse began to heave at the flanks, after which he staggered a few moments, and fell; when down, he breathed laboriously thirty-eight times in the minute, and, with scarcely a struggle, and not more than two minutes' delay, expired.

Some blood, obtained from the orifice in the jugular just before death, presented no abnormal appearances when subjected to microscopic examination.

Secio Cadaveris, 4½ P.M. The jugular vein and the right cavities of the heart were filled with dark coloured currant jelly-like clotted blood. The left cavities also contained a clot, but a much smaller one. Longitudinal section through both the lungs proved them to be intensely congested throughout, but most particularly at the bases; the apices and inferior borders were comparatively free. This cut surface was deep red; a large quantity of dark red blood exuded from it on pressure; the lung tissue thus congested floated on water.

It is important to notice that, from the manner the experiment was conducted, the introduction of air into the vein was impossible.

On examining the blood from the right side of the heart, I discovered on it a very large number of corpuscles, measuring, on an average, one two-thousandth of an inch in diameter, and having nuclei not distinguishable from those of pus-cells. So numerous were they, that it was impossible to count them.

EXPERIMENT IV, instituted on the horse which was the subject of Experiments I and II. Pressure over the lower part of the left jugular vein caused it to fill above, and blood flowed freely; on opening it between its bifurcation and the site of the first experiment on the 17th of October, a mixture of two drachms and a scruple of pus, diluted with an equal quantity of water, was injected into it on the 25th of October. A quarter of an hour afterwards, no change whatever had manifested itself; both in number and character, the pulse continued absolutely the same.

Oct. 27th. Pressure below the orifice, on the right side of the neck, caused the exit of half an ounce of good thick pus.

Oct. 29th. Since the last report, nothing whatever had occurred. The horse had fed, and appeared well, with the exception of occasionally coughing slightly. I ordered him to be destroyed by a blow on the skull, and proceeded to examine the body two hours after death.

Secio Cadaveris. On removing the skin from the right side of the neck, the tissues immediately beneath appeared perfectly healthy; but, on exposing the jugular vein, the cellular tissue around it was preternaturally red, and matted together down to its entrance into the chest, within which all was normal. On slitting open the vein, its coats proved to be of normal colour, smoothness, and thickness, except or about an inch in the situation where the aperture was

made; here a quantity of buff coloured plastic matter occupied about two-thirds of the calibre of the vessel, but the remainder was pervious. The subcutaneous tissues on the left side of the neck were likewise healthy; but, on exposing the jugular vein, it appeared as a white opaque solid body. On cutting it open, its coats were found much thickened, and intimately adhering to a clot, which occupied the entire bore, and gradually tapered downwards to the extent of about four inches, but barely extended half an inch above the orifice: beyond these parts, the vein was perfectly healthy.

The heart contained well clotted blood, and was perfectly healthy.

Both lungs were in the greater part healthy, but both contained abscesses in the posterior lobes. These abscesses were in every respect similar to those met with in individuals who have died from pyæmia: the majority of these were the size of peas, but one was as large as a walnut; its contents appeared good pus to the naked eye, and proved to be such on microscopic examination.

On the diaphragmatic surface of the posterior lobe of the left lung were numerous little tenacious shreds of lymph; but there was no preternatural redness of the pleura, or effusion into its cavity.

EXPERIMENT V, instituted Oct. 20th, on an aged but healthy white pony. An opening was made into the right jugular vein, and, after repeated endeavours to pass into it the nozzle of the injecting instrument, thinking I had succeeded, I injected a two ounce mixture of equal parts of water and creamy pus, but without any apparent effect.

Seven hours later, the constitution was not at all affected; but the neck below the aperture in the vein was slightly swollen, hot, and tender.

EXPERIMENT VI. No new symptom having made its appearance, at 1½ P.M. on the 27th of October, this pony was again experimented upon. A longitudinal incision was made over the course of the left jugular, a little above the middle of the neck; the vein exposed, pinched up with forceps, and opened; after which the nozzle was fairly passed into it, and a mixture of two drachms and one scruple of pus, with an equal quantity of water, injected. This was followed by acceleration of the respiration and pulse, the former of which, while the animal was standing half an hour after the experiment, numbered 30, and the latter 60 in the minute.

EXPERIMENT VII, 4¼ P.M. Respirations being 12, and pulse 60. The orifice made into the left jugular vein in the morning was reopened, and a mixture of one ounce and two scruples of pus, diluted with an equal quantity of water, injected. Ten minutes afterwards, the animal having just before got up, and being then standing, his respiration was 20, and heart-beats 64 in the minute.

28th Oct., 7¼ A.M. The animal continued standing. Pulse 76; respiration 36, laboured, and very decidedly abnormally thoracic. Immediately afterwards the animal was destroyed by a blow on the head.

Examination of the body three hours and half after death. The right side of the neck was scarcely at all swollen, but emphysematous crackling was detected on palpating it. On detaching the integument, the cellular tissue was found infiltrated with fetid bloody serosity from the angle of the jaw all over the side of the neck, in the bend of the elbow, in the deep cellular tissue which aided in connecting the shoulder to the trunk, and on the inner surface of the right foreleg down to the knee. The right jugular vein was filled with a smooth, dark red, non-adherent clot of moderate consistence. On detaching the integument from the left side of the neck, the cellular tissue was seen infiltrated with blood over a space of about two inches around the opening in the vein; beyond this part the subcutaneous tissues were perfectly healthy. The vein contained a common venous clot.

Heart. The right cavities contained a large amount of clotted blood, but there was barely a fourth of that quantity on the left side. On the left surface of the heart, opposite to the interventricular septum, were numerous little red

ecchymotic spots; some of these were bright red, others purplish. Microscopic examination of the blood from the right ventricle did not demonstrate any difference from the blood which was collected from the jugular vein prior to the injection of pus.

The *right lung*, on longitudinal section, appeared very much congested, particularly at the posterior and upper part; less so towards the apex and inferior border. The congestion was not quite so intense as it was in the horse suddenly destroyed by the injection of pus on 24th October, but it was very little less so. In the most congested part, the pulmonary tissue was not at all crepitant; yet it floated on water, even after firm pressure.

The *left lung* was in the same condition as the former, except that the congestion had posteriorly attained even a more intense degree. There were no nodules in either lung; the congestion was uniform.

From these experiments I infer:

1. That when pus is fairly injected into a vein, there is no obstacle to its moving on with the current of blood;

2. That the first organic effect of such injection is congestion of the lungs; which may be so intense as to prove instantly fatal, or be temporarily recovered from;

3. That the abscesses met with in the lungs of individuals who have fallen victims to pyæmia, may be produced by injecting pus into the veins of healthy animals.

Experiments for the purpose of ascertaining the effect of injecting pus into the bloodvessels have likewise been performed by Gaspard,* Trousseau and Dupuy,† Gulliver,‡ Renault and Bouley,§ Alan,|| d'Arcet,¶ Lebert,** Castelnau and Ducrest,†† Sédillot,‡‡ and Lee.§§ The results they have obtained are singularly contradictory; and it would appear as if the progress of time and the addition of experience have only served to augment the obstacles in the way of a definitive solution; for the most recent inquirer, Mr. Henry Lee, arrived at conclusions which tended to subvert those of Castelnau and Ducrest, and of Sédillot, who have particularly distinguished themselves for the number of, no less than for the manner of executing, their experiments. It is remarked by Mr. Lee that "the simple experiment of mixing some pus with healthy recently drawn blood, will at once show that such a combination cannot circulate in the living body. It will be found that the blood coagulates round the globules of pus, and forms a solid mass which will adhere to the first surface with which it comes in contact, and it will be evident that it is not till the coagulum thus formed is broken up or dissolved that its elements can circulate with the blood." Upon this passage I thus commented in a memoir on pyæmia, published in this JOURNAL for March 4th. "To argue, as Mr. Lee does, from the fact that out of the body blood coagulates round pus, therefore such a combination cannot circulate in the living body, is about as warrantable as it would be to predicate from the observation that pure blood coagulates in a basin, it therefore cannot remain fluid in the ventricles of the heart. The fact is, that the circumstances are so materially different, blood in an earthen vessel on the one hand, blood in the living body on the other, that no inference deduced in the one case is applicable to the other." The results of my experiments justify this criticism, and prove that the circulation of pus with the blood is perfectly possible.

Mr. Henry Lee has related seven experiments in which he injected pus into the veins, and they call for careful study. In the first of them (the vith of his series, *op. cit.*, p. 28),

three drachms of pure pus were injected into the left brachial vein of a healthy ass. When the operation was completed, the sides of the vein were brought together with a pin, and the animal was allowed to get up. The vein above the opening could now be felt as a hard unyielding cord, as high as it could be traced with the hand; but upon gentle pressure being made, so as to propel the blood in the course of the circulation, the hardness completely disappeared. Two hours and a half after the operation the pulse, which naturally was 36, had risen to 60; and the respiration, from 12 per minute, had increased to 26. The animal was destroyed two days after the injection.

Post Mortem Appearances. The wound in the left leg opened directly into the brachial vein, which was filled with lymph and a thin pus for a very short distance, both above and below the external opening. Immediately above this, the vein was healthy; nor was there any appearance of disease in any of the other veins of the limb, nor in the veins leading to the heart. The glands in the axilla were swollen. The lungs were found studded irregularly in different parts with circumscribed spots of livid congestion; these existed both upon the surface and in the substance of the lungs: they were generally about the size of a filbert, but in some places they occupied a single lobule, and were accurately circumscribed by its outline.

The result of this experiment, so far from supporting the doctrine propounded by Mr. Lee, is directly opposed to it. What was the cause of the vein above the opening feeling hard immediately after the injection, it is not easy to determine; that it was not due to the formation of a clot, is rendered more than probable by the fact that the hardness completely disappeared upon *gentle pressure*. Certain it is that the effects of pus circulating with the blood were speedily manifested by the acceleration of the respiration, not only absolutely, but also relatively to the increased frequency of the heart-beats. Thus: before the injection, pulse 36, respiration 12; two hours and a half after it pulse 60, respiration 36.

The *post mortem* appearances of the lungs, studded with spots of congestion, obviously the early stage of multiple abscesses, were characteristic of the entrance of pus into the circulation, perfectly concurred with my own experiments, and support the conclusions I have deduced from them.

In the second experiment (Exp. VII of series, *op. cit.*, p. 30), Mr. Lee, on Nov. 23rd, injected about an ounce of pus into the right jugular vein of an ass; the vein immediately became corded, and the blood appeared to have coagulated in the vessel. The operation did not much excite the breathing, but the pulse, which was naturally 35 in the minute, rose to 60.

Nov. 24th. The vein could be traced as a thickened cord as far as the sternum. Respiration 12 (the natural standard); pulse 90.

25th. The parts around the vein were much infiltrated with serum; pulse 50, respiration 12.

26th. The wound in the neck began to suppurate, and an abscess subsequently formed in the course of the vein about midway between the opening and the sternum. The general symptoms continued with very slight variation until the 4th of December, when the animal was destroyed.

Post Mortem Appearances. The jugular vein was found to have become inflamed only in the course of the circulation, and to be obliterated only a short distance below the external opening. The surrounding parts were greatly infiltrated with serum and lymph, and several abscesses had formed in the immediate neighbourhood. The lungs did not present any well defined patches of congestion, as in the last mentioned experiments.

Attentive consideration of the facts above recorded, makes it obvious that the pus was not injected into the vein, but into the surrounding cellular tissue. *a.* Though the pulse was accelerated, the respiration continued natural; this is the reverse of the former experiment, in which there can be no doubt that the pus did circulate with the blood. *b.* The serous infiltration of the surrounding parts noticed during life, and verified after death, with the additional discovery

of abscesses in the immediate neighbourhood, is precisely what occurred in my experiments II and V, in which dissection proved that the pus had been injected into the cellular tissue. The obliteration of the jugular vein, noted by Mr. Lee, is apt to occur from any cause which irritates the vein after an opening has been made into it. Thus, in experiments which I performed last year for the purpose of ascertaining the effects of injecting water and various saline solutions into the circulation, phlebitis occurred in several instances.

These observations are strictly applicable to Mr. Lee's VIIIth experiment; while, according to his narrative of experiments IX, X, XI, and XII, the injection of pus into the circulation was followed by such severe constitutional symptoms as to supply very weighty testimony in opposition to his teaching.

In restricting my analysis to the opinions of Mr. Lee, I have been chiefly actuated by a sense of their importance, based as they are on experimental researches, and opposed to conclusions, which ever since their announcement were regarded as marking an era in the progress of knowledge of the purulent infection. It was impossible to advance a step without admitting or refuting Mr. Lee's statements. To the latter duty, I have been led by careful experiments; the difficulty in conducting which has given me additional cause for respecting and being grateful to Mr. Lee for his endeavours to advance the knowledge of this highly important subject. In extenuation of not having as yet extended these researches, and analysed the opinions of all those who have hitherto engaged in them, I confidently appeal to the kind consideration of those who are acquainted with the nature of these investigations. I feel much pleasure in acknowledging the assistance I have received from my brother John, in the prosecution of the present inquiry.

PERISCOPIC REVIEW.

SURGERY.

TREATMENT OF ANEURISM AND OTHER VASCULAR TUMOURS BY THE INJECTION OF A SOLUTION OF PERCHLORIDE OF IRON.

During the present year, the attention of French surgeons has been closely directed to a new method of treating aneurisms, viz., that of producing coagulation of the blood in the aneurism by injecting a few drops of a solution of perchloride of iron into the sac. The merit of first bringing this method prominently under notice is due to the late M. PRAVAZ of Lyons. We propose to give an abstract of what has been said and written for and against this method.

History. In a letter to M. Marjolin, published in the *Union Médicale* for May 12th, M. Pravaz gives the history of the treatment.

The author states that, in the year 1828, he commenced experiments on the means of preventing the absorption of poisons. Cauterisation of the poisoned wounds by galvanism appeared to succeed best; this he first tried in cases of bites by vipers and by Indian snakes, and of mad dogs. In his experiments, he observed the readiness with which blood coagulated under the action of galvanism; but it did not occur to him to apply this principle to the treatment of aneurism until M. Velpeau had stated that a coagulum was produced by introducing a needle halfway into a vessel, and there leaving it. This led M. Pravaz, by a series of experiments, to the conviction that galvano-puncture was likely to be a very successful treatment; and he communicated his idea in 1831 to several surgeons. For many years this method remained in abeyance, being merely referred to in works on medicine and surgery; and it was not until 1845 that M. Pétrequin successfully employed galvano-puncture in aneurismal tumour in the course of the temporal artery. M. Pravaz observed with interest the applications of galvano-puncture which were made since 1845 in most countries of Europe. He was led to believe that this method, from the care which it required, from the frequent imperfection of the apparatus, and perhaps from a certain idiosyncrasy in the blood, often failed.

In 1851, he first attempted to produce coagulation by employing voltaic electricity as a means of conveying through the tissues one of the elements of a saline solution placed on the part. This plan had been partly proposed by Strambio in 1847. M. Pravaz thus describes his discovery of the treatment by injection of perchloride of iron.

"In the course of the experiments which I have related, the object of which was either to abolish acupuncture while galvanism was retained, or to reduce the operation to the introduction of a single needle, I observed that perchloride of iron instantaneously caused a solution of albumen to coagulate in mass. Considering, at the same time, that the preparations of iron are generally harmless when administered in a moderate dose, I was led to reflect whether, in place of endeavouring to suppress acupuncture in the treatment of aneurism, it would not be better to renounce electricity, and retain puncture as a means of introducing the coagulating material into the sac. I thought to realise that idea by means of the trocar which is used in the exploration of tumours. Those, however, which are in common use are not sufficiently delicate; and I waited the opportunity of a visit to Paris to have some made fit for the end which I proposed. M. Charrière perfectly fulfilled my wishes in this respect. I obtained also a small syringe, the piston of which was moved by means of a screw, so that the injection was performed steadily and continuously, and could be regulated at the will of the operator.

"On my return to Lyons, I attempted, with the assistance of my son, to produce coagulation of the blood in the carotid artery of a rabbit; but the artery was too delicate to allow the trocar to be easily introduced without transfixing it. . . . I had proposed to recommence my experiments on larger animals, when a severe illness interrupted my researches. They would probably have been altogether suspended, if the stay of M. Lallemand in my house had not both restored me to health and reanimated my scientific ardour."

MM. Pravaz and Lallemand then performed experiments in conjunction, in which M. Pétrequin participated for a time.

"The limits as to quantity which M. Lallemand and myself have determined, cannot be passed without producing symptoms of intoxication, and dissolution of the clot; but the injection of an excessive quantity may give rise to severe inflammation of the sac, consecutive ulceration, and expulsion of the coagulum.

" . . . M. Lallemand and I have estimated the quantity required to coagulate each centilitre (about one-fourth of an ounce) of blood as being three drops. I would even go below this limit; but, in order to furnish a sure guide to the operator, the degree of concentration of the solution of perchloride of iron must be observed."

In an article published in the *Gazette Médicale* for October 1, M. PÉTREQUIN of Lyons claims to share, equally with M. Pravaz, the merit of originating this mode of treatment. He states that, in 1845, he proposed to himself to search for an agent possessing the properties of fluidity, smallness of volume, capability of producing coagulation without carbonising the blood, non-liability to produce excessive irritation, and capability of being absorbed without danger. He also says that, in 1852, M. Pravaz proposed to him to perform a series of experiments with perchloride of iron. They performed some experiments in conjunction; but subsequently M. Pétrequin continued his researches independently; experimenting, however, with perchloride of iron and manganese. He does not, however, appear to have actually employed this agent in the treatment of aneurism.

The mode of operation is thus described by M. Lallemand:—"The method proposed by M. Pravaz consists in coagulating the blood in the vessels by the injection of a few drops of a solution of perchloride of iron at its maximum of concentration. The injection is effected by means of a very delicate trocar, which must be introduced very obliquely through the walls of the artery, by a kind of rotatory movement. To this trocar is fitted a syringe, of which the piston moves by means of a screw, so that the liquid may be injected steadily, and the quantity accurately measured. At the time of operating, the flow of blood in the vessel must be arrested." In the treatment of aneurism, the solution must be introduced into the aneurismal sac, and the artery must be compressed for four or five minutes.

Cases. At the meeting of the Academy of Medicine on the 8th Nov., M. MALGAIGNE read a paper on the treatment of aneurism according to the method of M. Pravaz. The article is published at length in the *Union Médicale* for November 10th. The author passed in review the history of the operation from the reading of a letter from M. Lallemand before the Academy of Sciences up to the present time. He referred to the experi-

ments of Lallemand, Giralès, and Debout, and to the cases of M.M. Raoult Deslongchamps, Niepce, Serre, Velpeau, Lenoir, Soulé, Alquié, Dufour, Jobert, and himself.

We have collected the reports of several cases from the journals in which they were reported; and shall avail ourselves of M. Malgaigne's Essay in the history of others. The whole of the cases from No 1 to XI inclusive, will be found in M. Malgaigne's paper.

CASE I. At the meeting of the Surgical Society of Paris on March 30th, M. LARREY related a case communicated to him by M. RAOULT-DESLONGCHAMPS. The disease was aneurism of the supra-orbital artery, of the size of a small pigeon's egg. It could be emptied by pressure. M. Deslongchamps injected a few drops of the concentrated solution of the perchloride, but at first failed, in consequence of the formation of a clot at the end of the canula. The next day, ten or twelve more drops were injected; and in three minutes the tumour became hard, and the pulsations disappeared. The swelling after this continued to diminish, until, at the end of a month, there was no trace of the aneurism beyond a little redness and slight thickening of the skin. (Abridged from *L'Union Médicale*, April 9, 1853.)

At a meeting of the Academy of Surgery on May 4, M. Larrey read a letter from M. Deslongchamps, in which the subsequent history of his case was reported.

On March 13, in the situation of the aneurism, the skin was a little more red and elevated than on the opposite side. There was also some thickening and induration. On April 15, M. Deslongchamps saw the man, who told him that he had been seized with a catarrh (from exposure to cold) on the 7th; and that he had had violent fits of coughing, which, in two or three days, caused the situation of the tumour to become more red and swollen. He also felt pulsation in it, which increased for a day or two. The cough then diminishing, the swelling and pulsation became less after the patient had worked some hours at his forge (which he had not ceased to do since discharged by M. Deslongchamps). On April 15, M. Deslongchamps sent for him, to ascertain the results of the operation. He then found that, in the situation of, or rather a little to the outside of, the primary affection, there was a flattened tumour, with ill defined edges, and very red, but not uniformly so. On applying the fingers, feeble pulsations were felt, but only on the lower half.

M. Deslongchamps did not think that this was a return of the disease, but merely a result of the enlargement of the collateral arteries, which had taken place in the formation of the original aneurism—in fact, an erectile tumour.

M. Robert at first, and afterwards M. Malgaigne, have doubted whether the tumour first operated on was an aneurism at all.

CASE II. On April 25, a case was related to the Academy of Sciences, which had been operated on by M. NIEPCE. The aneurism was popliteal; five minutes after injecting the perchloride of iron, the tumour became very hard; and, on removing pressure from the femoral artery, pulsation was found to have ceased in the sac. On the next and following days, there was severe inflammation in the parts operated on. On the eleventh day, fluctuation was perceived at the inner side of the tumour, and about two and a half drachms of purulent serum escaped on making a small puncture. On the twentieth day, the place of the tumour was occupied by a hard cicatrix of the size of a nut.

CASE III. At the meeting of the Academy of Sciences, on May 9, M. Lallemand communicated, for M. SERRE of Alais, the particulars of a case of varicose aneurism at the elbow, which had been successfully treated by the method of M. Pravaz. The clot was soon formed; pulsation did not return when pressure was removed from the bronchial artery; and, at a later period, pulsation disappeared in the radial and ulnar arteries. Inflammation, with suppuration, took place in the vicinity of the sac; an eschar was detached from the sac, without producing the least hæmorrhage; and cicatrization advanced rapidly.

M. Malgaigne acknowledges that in cases of M.M. Niepce and Seire—true aneurisms—the method appears to have succeeded. Yet the inflammation and suppuration of the sac in the former case, and the suppuration and sloughing in the latter, show that even these cases are not unattended with danger.

CASE IV. This case is given in the *Revue Méd. Chir.* for October 1853, and in M. Malgaigne's article. A student had false aneurism at the bend of the arm; it had followed a wound made in venesection. It had been present for three months, and was as large as a hen's egg. On May 21, M. VELPEAU carefully injected eight drops of solution of perchloride of iron, procured from M. Burin du Buisson. The consistence of the tumour appeared augmented; but, on removing pressure which had been applied to the brachial artery, pulsation returned. On June 11, ten drops were injected, but without success. The

tumour increased in size and became inflamed: and, on June 18, M. Velpeau tied the brachial artery. After a little trouble produced by ulceration, and discharging of clots from the tumour, the patient was discharged cured, on August 4th.

CASE V. On May 19, 1853, M. LENOIR operated for popliteal aneurism, on a man aged 62. He injected seven drops of the solution of perchloride of iron, without producing any effect on the pulsations. On May 31, sixteen drops were injected without results: and on June 18, twelve drops of M. Dubuisson's solution were used. On June 23, the patient was seized with pain in the affected part, attended with febrile symptoms. The pulsations had since the last injection become much weaker. On June 24, the popliteal region was hot, tense, and very tender; the pulse was 120; the skin very hot and dry; the patient moaned constantly; the superficial veins of the leg and thigh were more distended than usual. The patient was bled, and poultices and mercurial frictions were applied to the tumour. The symptoms went on increasing; extreme prostration and delirium appeared; and the patient died on June 28th.

An examination of the body showed numerous points of ossification on the artery. Blood was effused all round the tumour, and in the neighbouring muscles. The swelling was hard, and was filled with a sanguineous mass, adhering to its walls. The femoral vein, at the level of the tumour, was flattened, and almost impermeable; higher up, it was filled with a sanious fluid, which did not extend into the veins of the pelvis. The pericardium contained some serosity, and presented traces of old pericarditis.

CASE VI. A patient was admitted into St. Andrew's Hospital at Bourdeaux, with aneurism of the femoral artery. M. SOULÉ injected four drops of a solution of perchloride of iron. The tumour immediately became hard. Compression was maintained for a quarter of an hour; when it was removed, pulsation immediately returned. Moderate pressure on the artery was kept up; and, five days after the first operation, M. Soulé injected seven drops. On this occasion, severe pain was produced; the patient could not sleep; the tumour inflamed and increased in size; and complete coagulation could not be obtained. Fearing ulceration and hæmorrhage, M. Soulé tied the femoral artery about five weeks after the last injection. The patient recovered.

CASE VII. In a case of traumatic aneurism, of the size of a cherry, seated on the posterior tibial artery, near the internal malleolus, and from which there had several times been hæmorrhage, M. SOULÉ injected some of the solution, and plugged the wound with some charpie impregnated with it, and applied a compress. In three days, no result having been produced, he opened the tumour, and found that the artery had completely divided. It could not be tied; but pressure by means of plugs of charpie dipped in Pagliari's solution was successful.

CASE VIII. M. ALQUIÉ of Montpellier relates the following case in the *Revue Thérapeutique du Midi*. M., aged 50, accidentally wounded his ulnar artery on June 20, while cutting wood. On July 16, there was a pulsating tumour of the size of a pigeon's egg on the upper part of the hypothenar eminence; it was covered by a small suppurating wound. On the 20th, five drops of solution of perchloride of iron, with five drops of water, were injected: and a compress dipped in the solution was laid on the tumour. The pulsation diminished, but did not entirely cease. On July 21 and 22, there was severe pain, and the pulsations had become stronger. On the 23rd and 24th, erysipelatous redness, accompanied by swelling and tension, extended from the hand to the elbow. The symptoms went on increasing; and, on the 27th, there was an escape of purulent fluid at the seat of the tumour: ulceration was also extending along the forearm. On the 29th, the pulsation in the tumour continuing, and signs of impending rupture appearing, the brachial artery was tied. The pulsation ceased, but reappeared on August 2nd; and on the 7th, copious hæmorrhage took place from the wound over the aneurism. The ulnar artery and a collateral branch were tied at the lower part of the arm. After this, the pulsations were arrested; the tumour diminished; and the patient was discharged cured on September 18th.

CASE IX. M. DUFOUR thrice injected a large aneurism of the right carotid artery. Violent inflammation was produced; the tumour sloughed and burst, and the patient died of hæmorrhage. (*Annales Cliniques de Montpellier*, 10th April, 1853.)

CASE X. M. JOBERT has operated on a patient; gangrene and death supervened. The particulars of this case have not yet been published; it is merely mentioned by M. Malgaigne.

CASE XI. M. MALGAIGNE (*loc. cit.*) relates a case which came under his own care in the Hôpital St. Louis. A workman in a soda-water manufactory, aged 20, was admitted, on July

30th, with traumatic aneurism at the bend of the elbow. M. Malgaigne at first applied pressure without effect; and was deterred from applying the ligature by the fear of producing gangrene, especially as the median nerve had been injured. He then determined to inject the sac; taking the precaution of applying pressure *above*, in order that coagulation might not be prevented by the impulse of the blood sent from the heart; and *below*, that the injected matter might not be carried into the small ramifications of the vessel. He was obliged to puncture the tumour in several places before he could arrive at its interior. He injected five drops; compression being removed, pulsation was not felt in the radial; but in the course of the day it returned. The punctures healed readily; but on the fourth or fifth day the patient complained of severe pain in the interior of the sac; in three days it had become very severe, and the sac was much enlarged, and had a blackish spot on its surface. Fearing that rupture might take place, M. Malgaigne applied a ligature, with some difficulty, from the inflammatory engorgement of that arm. Pulsation immediately ceased in the tumour and in the radial artery. The patient had erysipelas of the arm, and rheumatism in the knees, which were successfully treated by poultices and veratrine. After some days, finding that the tumour did not diminish, M. Malgaigne opened it, and removed a large coagulum, which contained only blood-corpuscles.

In some remarks made with reference to his case (case v) (*Gazette des Hôpitaux*, Oct. 25th), M. LENOIR, after describing the instrument of M. Pravaz, and the manner of using it, said that it did not act so exactly as he could desire. A clot of greater or less density would be formed in the canula of the syringe by the solution of perchloride meeting the blood; and the resistance thereby produced is sometimes so great as to force back the whole of the injection behind the piston. In either case, it would not be possible to form any other than an approximative idea of the number of drops injected.

To remedy the first inconvenience—the obstruction of the canula by a clot—M. Lenoir fitted to the syringe a long canula, capable of being introduced through the canula of the trocar. With this canula, the solution is introduced into the current of the aneurismal sac, without risk of coagulating the blood in the canula of the trocar. To ascertain whether there was any reflux of the fluid behind the piston, M. Lenoir has used a glass syringe, so as to observe all that passes in its interior.

There is, according to M. Lenoir, another difficulty, viz., to be able to introduce the point of the instrument precisely into the blood in the aneurism. In his own case, he failed in at once reaching the blood; and he believes that he introduced the instrument into the fibrinous deposit in the interior of the sac. The repetition of exploratory punctures, he justly observes, might produce inflammation and suppuration of the aneurism. This difficulty of finding the interior of the sac may not always present itself; but M. Lenoir would be inclined, if it should again occur to him, to inject the hemostatic fluid into the part of the artery immediately above or below the aneurism. In this way, there would be only a small quantity injected, a healthy part of the vessel would be operated on, and the same results would be produced.

M. Lenoir also referred to the danger of wounding important structures in the vicinity. In his own case, he seemed to have injured the vein—probably in one of his exploratory punctures; and this was more likely, as the vein was flattened, and adherent to the aneurism, and almost impermeable to blood; hence giving no indication of its locality.

Dangers, Difficulties, and Precautions. In the *Bulletin Général de Thérap.* for May 15th, Dr. DEBOUT, the editor of that periodical, offers some remarks on the subject. He had performed some experiments with the view of determining how much of the solution of perchloride of iron could be used without producing arteritis. He describes the appearances found in a horse, into whose right carotid he had injected seven drops, and into the left fifteen drops. The calibre of the right carotid artery was free, and its lining membrane quite healthy. The left carotid, on the other hand, presented redness, thickening of the membrane, and deposit of pus, with which was mixed the debris of the coagulum.

Dr. Debout points out the importance of *pressure* as an auxiliary, in preventing the coagulum from being broken up by the current of blood. Three or four years ago, he produced coagulation of the blood in a false aneurism at the bend of the arm. Pressure on the humeral artery was not maintained; and the clot was redissolved. Unless pressure is maintained, he believes that, to produce a clot capable of resisting the current of blood in men, it will be necessary to use such a quantity of the solution of perchloride of iron as will expose the patient to the

danger of arteritis. If proper precautions be observed, Dr. Debout is in favour of the operation.

At a meeting of the Academy of Sciences, on May 9th, M. LALLEMAND observed that "the success which had already attended M. Pravaz's method of treatment confirmed him in his opinion of its superiority to all other methods. He was firmly persuaded that the method of injection would produce as complete a revolution in the treatment of aneurism as lithotripsy had produced in the treatment of calculous diseases. The first instruments used in the latter operation were complicated and imperfect; and for a long time successful cases were mingled with severe accidents and numerous reverses; but now lithotripsy is not what it was at its commencement. It will no doubt one day be the same with the method of M. Pravaz."

M. DEBOUT also expressed himself in favour of the operation when performed with proper precautions, such as those to which we have already referred.

M. MALGAIGNE is an opponent of the method. He points out in his paper which we have quoted, that in eleven cases, four died, eleven had severe symptoms, and two were successful. He concludes in the following terms. "With regard to aneurisms, although the possibility of curing them by the injection of perchloride of iron be placed beyond doubt, the successful cases are so rare, obtained at the price of so many accidents, and counterbalanced by so many reverses and even by deaths, that at present I think that no prudent surgeon could expose his patients to the results of such a disastrous mode of treatment."

An animated discussion followed the reading of M. Malgaigne's paper.

M. MOREAU believed that the operation ought to be at once and totally discarded.

M. ROUX and M. VELPEAU agreed that there was little evidence as yet in favour of the operation; but would suggest a more extended course of experiments.

We do not entirely agree with the sweeping condemnation of M. Malgaigne; and would prefer following, and recommending our readers to follow, the more moderate advice of MM. Roux and Velpeau. Yet the operation is one which should not be undertaken without due reflection on its possible dangers, nor until treatment by compression has been tried and found ineffectual. As regards the relative merits of injection and ligature—the former appears at first sight to possess an advantage over the latter, in not involving impediment of the circulation in any collateral branches which may be given off between the aneurism and the seat of ligature.

The principal difficulties in the operation appear to us to be: *first*, to determine the quantity of the fluid which shall, when injected, coagulate the blood, and at the same time set up only a moderate degree of inflammatory reaction in the walls of the aneurismal sac; *second*, to ensure the non-removal of the coagulum. The first of these can only be removed by experiment and experience; and, with regard to the second, we would advise any surgeon who performs the operation of injecting an aneurism, to maintain for some time moderate pressure on the artery above the aneurism—sufficient to moderate the flow of blood, yet not so great as to entirely cut off the supply.

Treatment of Varix. The solution of perchloride of iron has also been employed in the treatment of varix. M. PÉREQUIN has injected the perchloride of iron and manganese in several cases of varicose enlargement of the saphena vein. The effect produced was obliteration of the vein.

In the *Bulletin de Thérapeutique* for September 15, Dr. DEBOUT refers to six cases of varicose veins operated on by M. Desgranges of Lyons. In five, there were no remarkable symptoms; but the sixth patient died, after an attack of inflammation of the whole upper third of the leg.

This plan of treatment is worthy of further investigation. In the mean time, the following remarks, by Dr. Debout, should be borne in mind.

"It is not enough that the operation succeed, and that the patients leave the hospital cured of the disease on account of which they have been admitted. The cure must be permanent. If, after a longer or shorter interval, the disease reappears, the performance of the operation has been a mere waste of labour and time; and it becomes the duty of the surgeon to abandon the plan, however innocent it may appear to be. In the Bicêtre, we have seen a great number of old persons, in whom the obliteration of varices had been in vain attempted. After a greater or shorter lapse of time, they were always reproduced. When the calibre of the vessel is closed at one point, the blood takes another course; distends the small veins. If these anastomoses are not actually developed, so as to reproduce the disease, they

at least serve to convey the blood into the varicose vein below the obliterated portion... In making these remarks, we only wish to call the attention of surgeons to all the elements of the problem which they attempt to solve."

TREATMENT OF VASCULAR TUMOURS BY INJECTION OF LACTATE OF IRON.

In the *Lancet* for August 20, 1853, Dr. BRAINARD of Chicago, U.S., relates the case of a man, aged 34, who came under his care in August 1851, with an erectile tumour in the left orbit. Dr. Brainard tied the left carotid artery, and punctured with hot needles; but these remedies failing, he determined to inject a solution of the lactate of iron. This was done on Dec. 14th, 1852. He thus describes the operation and the subsequent progress of the case.

"A solution of the lactate of iron, of the strength of eight grains to one fluid drachm of distilled water, filtered through paper, was prepared.

"Dec. 14th. I punctured the tumour at its most prominent part with the infiltrating canula, carrying it to the depth of about an inch; on withdrawing the stylet, arterial blood followed. A fluid drachm of the abovenamed solution was immediately thrown in with a small syringe, constructed for the purpose, and the canula withdrawn. The immediate effect was an intense pain in the left temporal region and a flushing of the face, which latter only lasted a few seconds. A chill followed, accompanied with nausea and vomiting. Reaction took place in an hour, but the vomiting continued, and for twenty-four hours all drinks were ejected; pulse 63.

"Dec. 15th. Vomiting continued; the pain was less; the upper lid was much swollen; pulse 65.

"Dec. 23rd. For the last six days, the vomiting had gradually diminished; the pulse was natural; the tumour was less tender, firm, and the pulsation was perceived only at the external angle; frequent lancinating pain was felt in the orbit.

"During the whole of this treatment, both of punctures and infiltration, the head was kept enveloped in bladders filled with a freezing mixture of pounded ice and salt, which was very grateful to the patient. He now began to complain of its being too cold. The heat in the head was reduced to the natural standard, and from the time of the infiltration neither thrill nor sound has been perceived. The veins of the face were much diminished in size, and the pulsation of the arteries reduced to its natural state. A slight pulsation was still perceptible at the external angle of the eye, for which a puncture was made at that point with a hot needle, on January 4th, 1853.

"Jan. 10th. From the time of the last puncture, no pulsation had been perceived, the swelling subsiding. At this time an opening was found to exist on the anterior surface of the globe of the eye, which still remained protruded between the lids. This was followed by severe inflammation of the globe, which lasted several days. The discharge from the opening was at first the humours of the eye, afterwards pus, but no blood.

"June 6th. The patient had been pursuing his ordinary occupation for three months; his health appeared perfectly restored. The left orbit seemed entirely free from disease."

On the comparative merits of the perchloride and lactate of iron as a means of producing coagulation of the blood within the vessels, Dr. Brainard makes the following remarks:—

"If we take into consideration that the solution of the perchloride of iron is a substance foreign to the normal constitution of the blood, and produces instant coagulation when brought in contact with it, whereas the solution of the lactate of iron is composed of elements which enter into the composition of the blood; that when thrown into the living vessels it does not coagulate it, but produces a thickening of the coats and a deposition of coagulable lymph from subacute inflammation; the difference between the two results will be readily understood. It is probable that the solution of the lactate, when thrown into the vessels, immediately undergoes decomposition, the acid combining with the soda of the blood, and the base passing into a higher state of oxydation, in which it naturally exists in that fluid. In no case has this solution, when thrown into the blood or into a vascular tumour, shown a tendency to produce suppuration, but in slow inflammation of an adhesive kind and limited extent. In one case, where it was inadvertently pressed in small quantity into the subcutaneous cellular tissue, instead of into the vein as intended, a hard swelling, having all the appearance of a boil or small carbuncle, was the result; but even this effect will not be produced by it, when used in that manner, unless the solution be in a certain degree concentrated."

TREATMENT OF DISLOCATION COMPLICATED WITH FRACTURE.

In the *ASSOCIATION JOURNAL* for April 29, we noticed briefly M. RICHET's Memoir on the possibility of reducing dislocation of the humerus and femur, when complicated with fracture; and we also gave a full abstract of M. MALGAIGNE's observations on the same subject. We now quote from the *Mémoires de la Société de Chirurgie de Paris*, tome iii, fasc. 4, the following case and observations, furnished by M. Richet.

In September 1851, a man aged 68 years came to M. Richet, with a dislocation of the upper extremity of the humerus, with fracture of the anatomical neck of that bone. He was then in a state of complete intoxication; but the next morning he was able to communicate the following details. He was descending a narrow stair-case, when his foot suddenly tripped and he fell backwards. In this fall, the left shoulder struck the angle of one of the steps; and when the man was lifted up, he could no longer use his arm, which was perfectly serviceable before the accident. This man was very thin, and his limbs were easily examined. In front of and rather lower than the left acromion there was an evident angular projection, at the summit of which was a deep ecchymosis, having a transverse direction; this was the point in which the patient said that he had fallen. Behind and below the acromion was a visible depression, into which the index finger penetrated with facility, proving that the head of the humerus had passed out of the glenoid cavity. Above this depression the acromion formed a well marked projection, particularly when compared with the corresponding part of the opposite side. On carrying the hand into the axilla, it first encountered a hard cord, stretched from the posterior border of the axillary cavity to the anterior, a little obliquely from below upwards and from behind forwards; this consisted of the flattened tendon of the latissimus dorsi. More posteriorly and internally, another thicker projection was observed. By carrying the hand to the summit of the axillary hollow, a tumour was found of an irregularly round shape, moveable, and apparently isolated, for it could be moved in all directions. Suspecting that this tumour was merely the head of the humerus thrown out of its cavity, M. Richet rotated the lower end of the bone, but the tumour was not at all moved, nor was any crepitation perceived. These rotatory movements produced very great pain; and on applying the hand to the angular projection above described at the anterior extremity of the shoulder, it was found to be affected by the rotatory movements impressed upon the inferior extremity of the humerus; this led M. Richet to ascertain that it was formed by the upper end of a fragment belonging to the body of the humerus. It was irregular, with rather well-marked dentations, some of which were entangled with the fibres of the deltoid. The movements of abduction and elevation were impossible; and flexion of the fore-arm upon the arm was effected with great difficulty.

The case was therefore evidently one of fracture of the surgical neck of the humerus, complicated with dislocation of the head of the bone. As the pain in all the muscles surrounding the shoulder-joint produced contractions, which prevented the apposition of the two fragments, the patient was put under the influence of chloroform, to obtain, if possible, a complete resolution of this muscular action, and to enable the examination to be concluded. In less than two minutes, the patient became quite insensible, with complete relaxation of the muscles; it was then easily ascertained, 1st, that the head of the humerus was dislocated into the summit of the axillary hollow, where it formed an irregularly rounded tumour, very moveable, and detached from the rest of the bone; 2nd, that the upper end of the lower fragment of the humerus was displaced forwards under the deltoid; 3rd, that there was another little fragment completely detached, but entangled in the fibres of the deltoid, and which had not previously been detected, in consequence of the contraction of this muscle.

After the patient was restored to consciousness, the lower portion of the bone was easily disengaged from the fibres of the deltoid, and crepitation was then perceived.

On the 12th of September, the patient was again put under the influence of chloroform. Taking advantage of the complete relaxation of the muscles, which ensued in a minute and a few seconds, M. Richet seized the man's arm; and, bringing it forwards and downwards, he disengaged very easily the upper extremity of the lower fragment from the deltoid fibres. The arm was then entrusted to an assistant, and M. Richet grasped the convexity of the shoulder with both his hands, the two thumbs resting on the acromial projection, while, with the four fingers

of each hand directed towards the summit of the axilla, he endeavoured by careful efforts to bring back the head from within outwards towards the glenoid cavity. Notwithstanding the slight hold afforded by the fragment, it was felt to be yielding by degrees, and the reduction was soon completed, without any noise, and rather insensibly than suddenly. After that time the two fragments remained in contact, and the regular rotundity of the shoulder was completely restored.

The next morning an apparatus was fitted, consisting of an axillary pad made of charpie covered with a compress, carried up to the summit of the axilla, in order to prevent any fresh displacement in this part. The fore-arm was bent upon the arm at an acute angle, and the hand placed upon the sound shoulder, so that the lower extremity of the humerus being carried forwards, the upper extremity of the fragment was carried backwards in an opposite direction to that which it formerly took. The contact then appearing to be as perfect and secure as possible, the parts were fixed in this position by means of a bandage, which left uncovered the convexity of the exposed shoulder, in order to allow the observation of any changes which might subsequently occur in this region.

On the 13th of September, the patient had slept well, and the shape of the shoulder was perfectly natural. On feeling the part, a rather considerable effusion of blood was found to have taken place into the articulation, and the splinter formerly mentioned was now perfectly appreciable at the anterior and external part of the shoulder.

On September 4th, and following days, no new symptom occurred. The patient ate well and slept well; but he complained of numbness in the arm and fore-arm.

On October 4th, the effusion of blood had disappeared. The bandage was removed when it was ascertained that the reunion of the fragments was effected, and a simple sling was applied, which allowed of slight movements, sufficient to prevent ankylosis, but not sufficient to break the callus, or even to retard its formation.

On October 30th, the bandages were removed, and the patient had a bath: the callus was perfectly solid, but the movements in the scapulo-humeral articulation were almost annihilated; and it was, in fact, observed, that the movements of the arm were effected by the sliding of the scapula upon the thorax. The patient was, however, recommended to exercise the arm as much as possible.

On November 24th, the patient was still in the hospital; and it was found that there was a very well marked degree of mobility in the scapulo-humeral articulations, which gave hopes of still further power of motion. The splinter formerly described remained still detached and moveable, but, every time it was disturbed, the patient experienced severe pain. The numbness of the arm and fore-arm had almost disappeared.

On June 27th of the next year, the patient came to the hospital for another complaint. It was then ascertained that he had very little difficulty in moving his shoulder; he lifted his arm easily to his head, and executed all the other movements which he was directed to perform, without experiencing the slightest pain. The splinter had disappeared, or at least was hidden among the deltoid fibres, which had become developed by exercise to such a degree, that the rotundity of the shoulder, compared with that of the opposite side, was perfectly normal.

M. Richet, in commenting on this case, comes to the following conclusions:—

1. That, contrary to the opinion universally adopted, dislocations of the humerus and of the femur, complicated with fracture of the extremity of the dislocated bone, may and ought to be reduced immediately; and the fracture, thus brought back to a simple state, should be treated like other solutions of continuity of the bone.

2. That, to perform this reduction, the patient should be subjected to the most complete anæsthesia, in order that the muscular action may be entirely annihilated; and that, of all anæsthetic agents, chloroform appears hitherto to be the best.

3. That clinical experience, reasoning, and experiments upon the dead body, agree in demonstrating that, as the muscular power is the principal, and, in fact, the only obstacle to the replacement of the bone, so, when this is annihilated, it is not necessary to employ a lever of greater or less length to apply to it forces of extension, but that it is then sufficient to exercise directly upon the dislocated extremity pressure which may push back the head of the bone into the articular cavity.

4. That, in the very rare cases in which the fibrous tissues form an obstacle to the replacement of the bone in its cavity, it is to this method of pushing back the head that we must have

recourse by preference, as being more rational and more efficient than extension.

5. That, if the proceeding by extension is to remain as a general method in the treatment of dislocations without fracture, yet we must admit that the proceeding by pushing back will be always, even in such cases, a powerful auxiliary; and further, that alone it is applicable, to the exclusion of extension, in the treatment of dislocations complicated with fracture of the dislocated bone.

SURGICAL USES OF PERCHLORIDE OF IRON AND MANGANESE.

In the article in the *Gazette Médicale* to which we have referred, M. PÉTREQUIN says that perchloride of iron and manganese is capable of being usefully applied to several purposes in surgery.

To *atonic ulcers*, compresses, wetted with a solution of the chloride, have been applied with benefit.

Foul ulcers are cleansed, and their appearance is changed.

The odour of *sloughing* wounds and foetid suppurations is rapidly removed by it. M. Pétrequin believes that it would hence be a highly valuable agent in hospitals, where it is important to remove all foci of infection and miasmatic influences.

The solution of perchloride of iron and manganese is very useful in the treatment of patients who are threatened with *purulent infection* from wounds.

M. Pétrequin states that, since he used this solution to dress stumps after amputation, when the suppuration was becoming foetid, he has not seen a single case of purulent infection among them, and has not lost a patient.

It has also proved useful in certain cases of internal hæmorrhage, and some adynamic affections; and he believes it to be indicated in certain asthenic diseases of the blood.

DIAGNOSIS OF RHEUMATIC ORCHITIS.

In the *Revue Thérapeutique du Midi*, Dr. RAYMOND FAILLOT gives, after Professor Bouisson, the following diagnostic signs of rheumatic orchitis. We quote from the *Gazette Médicale* for Nov. 5.

Inflammation of the testicle, the result of blennorrhagia, arises in the course of a slight discharge, which has already existed for some time: rheumatic orchitis rarely coexists with urethritis. The epididymis is the first part attacked in inflammation consecutive to urethritis; it is not often engorged in rheumatism. In general, inflammation of the testicle affects the organs of only one side; both organs may be at the same time attacked in rheumatic metastasis. Orchitis following urethritis rarely passes in an abrupt manner from one side to the other; the contrary has been observed in rheumatic orchitis. The fever and the severe pains are increased by the slightest pressure in the former disease; in rheumatic orchitis there is no fever, and the pain is not increased by pressure, which shows that the disease is not inflammatory. In venereal (gonorrhœal?) orchitis, all the tissues are attacked; in rheumatic orchitis, the fibrous tissue alone is the seat of disease. In gonorrhœal orchitis, the treatment must be chiefly antiphlogistic; in rheumatic orchitis, the employment of local antiphlogistics is not imperiously demanded.

OPHTHALMOLOGY.

TREATMENT OF SCROFULOUS OPHTHALMIA BY IODINE VAPOUR.

We regret that the notice under this head in our "Periscope" of Oct. 7, should have been printed without the remarks we meant to have appended to it, to the following effect. We consider that the advancing of this proposal proves that the author of it has thoroughly studied neither scrofulous ophthalmia nor the general principles of therapeutics, and we therefore quote it rather in warning than in approbation. We think that there is no more important principle in medicine than this, that no such disease is single (simplex) in its nature, or to be treated by one remedy; but that in almost every malady we have a complication of different pathological elements, which must be analysed in every individual case, that we may meet them with those means severally adapted to combat each. In scrofulous ophthalmia, more conspicuously perhaps than in any other disease, we have this variety; one case is more inflammatory, and must be treated by leeches and antimony, another is to be met by emetics, a third by purgatives, a fourth by quinine, a fifth by belladonna: locally, one case demands soothing, another stimulating, a third astringent applications. Judge, then, of the ophthalmological skill of the man who proposes the highly stimulat-

ing vapour of iodine as the panacea for all! In certain atonic cases we have no doubt it may do good; in many others we have as little that it would do irretrievable harm; and giving the author of the proposal all credit for a faithful record of his experience, we can but wish that it had been a little more extended before he rushed abroad to proclaim it; and that above all he was rightly impressed with the value and necessity of constitutional treatment in these diseases.

PRISMATIC SPECTACLES IN STRABISMUS.

Mr. SPENCER WELLS has addressed to us a note in explanation of his paper on this subject. We regret that in the attempt to be brief we failed to be clear in explaining our views on the matter in our "Periscope" of Oct. 7. The difficulty we had was not in comprehending that the cure is sought to be effected by altering the direction of the rays incident into the eyes, and so the position of the image on the retina; but in convincing ourselves that this will be followed by the desired improvement.

The squinting has originally come on *in spite* of the necessary displacement of the image, and in many cases the impression on the faulty eye is altogether neglected. In a case at present under our care, the patient has but *one* eye, and with this he squints inwards most distressingly, although by an effort the eye can be pretty well abducted. To produce the effect desired, the prism must obviously be arranged so as to throw the image still further from the axis of the eye, and therefore into a *less* sensitive part of the retina, where it is, of course, still more likely to be altogether neglected.

But we are very far from supposing that this theoretical difficulty is conclusive against the new mode of treatment: we only thought that it drove us back upon experience as the true test of its utility; and as we now understand Mr. Wells, he acknowledges that it is in slight cases only, in which, from the very slightness of the deformity, the patient is unwilling to submit to the division of the tendon, and the surgeon to recommend it, that he looks for success from the employment of the prismatic spectacles. In such cases, we think that the above-mentioned difficulties will stand much less in the way, and repeat that we shall rejoice in having a series of cases in proof of the utility of this very ingenious device.

SPONTANEOUS DISLOCATION OF THE LENS INTO THE ANTERIOR CHAMBER OF THE EYE, PRODUCING CEREBRAL DERANGEMENT.

In the *Canada Medical Journal* for January 1853, we have an account of the following case, by Mr. HENRY HOWARD.

Mary M., aged 34, servant, unmarried, admitted November 20, 1852, stated that, since about the 1st of May, she had been suffering severe pain and inflammation in her left eye, which pain had, for about the last three months, attacked the head. It was at periods so severe as to deprive her of her senses, and render her life miserable. For a long time she had had no wish for food, and had had constant attacks of vomiting for the last three weeks. Sight had long since disappeared from the diseased eye; she was certain that her eye never received any injury, and that it was never inflamed before the present attack.

When she presented herself at St. Patrick's Hospital, her appearance was that of a poor, miserable, emaciated creature, worn out by disease and suffering; she was not able to walk without assistance, and was vomiting every few minutes. Her pulse was small and rapid, varying from 95 to 100; tongue furred. On examining her left eye, I found the whole eyeball was inflamed, and the lens, with a small quantity of lymph, lying in the anterior chamber. Believing that the cause of all her sufferings was the pressure produced by the dislocated lens, I determined to remove it at once by extraction, and without delay made a section of the lower half of the cornea, which evacuated the hyopium at the same time that it enabled me to remove the lens with but very little trouble. The after treatment was the same as that adopted after extracting an ordinary cataract: on the twelfth day, the wound of the cornea was perfectly healed, and all the inflammation subdued. From the moment of the operation, there had been no more vomiting; the head symptoms gradually subsided, and completely ceased after forty-eight hours. The eye has now the same appearance as the sound eye, and for the last week sight is gradually returning. The remarkable points in this case are: First, all the cerebral symptoms produced by dislocation of the lens into the anterior chamber of the eye, are such as would be found from tumour in the orbit, causing distension of that cavity, or what would arise from malignant disease of the eyeball. Secondly, the lens being spontaneously dislocated as the result of long continued inflammation, which inflammation must, as a matter of course, pro-

duce destruction of the capsule of the lens, is a strange result of inflammation of that part. From the patient's own account, I concluded that the lens was not dislocated from the commencement of the attack, but for the last three months, which was the length of time she had been suffering from severe head symptoms, and lost her sight.

Of this case we take the liberty to offer the following paraphrase:

Mary M., etc., was admitted suffering under severe "neuralgia ophthalmia" (Jacob) of the left eye, of which the lens was lying in the anterior chamber, though when it got there the history of the case is not sufficiently precise to enable us to say. The hemispheres were intense, and there was constant vomiting, nervous prostration, and emaciation, but no cerebral symptoms. Extraction of the lens was of course at once performed; and, to our satisfaction, was followed by complete disappearance of the inflammation, and some return of sight. The case, though not unusual, is interesting.

THE TREATMENT OF POSTERIOR DISPLACEMENT OF THE LENS.

Mr. Dixon has published in the *Lancet* for October 1, a paper upon this subject, in which he records two cases of dislocation of the lens into the "posterior chamber", by which he means, as the cases show, the chamber of the vitreous body.

In the first case, a lens which had been cataractous for forty years, fell suddenly into the semi-fluid vitreous humour, and was hooked out through a section in the cornea. Much of the vitreous humour escaped; and the eye, though it healed well, remained blind.

In the second case, a lens, dislocated into the anterior chamber by a sudden blow, slipped back through the pupil, and was found rolling about behind it. The lens having been partially broken up, by means of two needles introduced through the sclerotic at opposite sides, was allowed to dissolve for about five months, when the residue was extracted through the cornea, and tolerably good vision preserved.

The cases appear to have been judiciously treated; but there is no particular novelty in the operation proposed. We have performed similar operations, and seen them performed, in like cases, and with rather more success.

DIAGNOSIS OF INCIPIENT CATARACT.

In the young this is easy; but in the old, as Mr. HAYNES WALTON shows in a clinical lecture, of which notes are published in the *Medical Times and Gazette* for October 1, the matter may be more difficult. In old persons the lens usually undergoes a change, independently of cataract, becoming amber coloured, and in this state producing a reflection behind the pupil, which may be mistaken for incipient cataract. The catoptric test Mr. Walton considers as worse than useless in these cases, because the non-cataractous amber coloured lens produces a confusion and dimness of the images, such as may also arise from cataract in its early stage; and therefore our diagnosis must, he thinks, be made with great caution, and chiefly from the powers of vision, the amber non-cataractous lens not hindering the patient from seeing well. As he is usually presbyopic, we should select objects at some distance, and not a printed book, as the tests. We need not say that the frequent coincidence of slight amaurosis with the non-cataractous amber state of the lens, and, on the other hand, the fact that this amber change shades off into true ("glaucomatous") cataract, tends to increase the obscurity of many of these cases, and to show how cautious we ought to be in forming our diagnosis.

MECHANICAL REMOVAL OF OPACITIES FROM THE CORNEA.

In the *Medical Times and Gazette* for November 5th is published a Clinical Lecture by Mr. HAYNES WALTON, on the removal by operation of a particular kind of corneal opacity.

Elizabeth Wheeler, aged 20, had been a patient at the Central London Ophthalmic Hospital since 1845, and, in 1852, was virtually blind, requiring to be led, and unable to perform any act requiring sight. The centre of each cornea, to an extent a little beyond the pupil, was occupied by a dense opacity, slightly raised, and giving in profile somewhat of the appearance of "conical cornea". The form of each was irregularly spherical, with sharp outline; the colour, French white, with dots or mottling. The remainder of each cornea was transparent; otherwise, the eye seemed healthy. When the pupils were dilated, she could see to move about the house alone, but that was all. Her blindness was of about ten years' duration. Mr. Walton determined to attempt removal of this opacity by picking it

away gradually with the miniature gouge described and figured in his work on *Ophthalmic Surgery*. He selected the right eye, picked away at the outer margin of the opacity, detaching some of it, which proved to be superficial. Finding the attempt in so far successful, that the cornea remained transparent in the part operated on, he repeated the process four times, at intervals of a month, operating also twice on the left eye. The result was, that, with the right eye, she could read large type. The woman ceased to attend till the present summer, when he operated twice on the right, and several times on the left eye. Now, the appearance of the eye is so far natural, that it needs a careful examination in a favourable light to detect the remaining opacities. The form and outline of the cornea are normal, and their entire surfaces reflect the light. Vision is nearly perfect. With either eye, she can thread a common sewing needle.

This is a very interesting case, and well calculated to encourage us to give further trial to the operation which Mr. Walton has so successfully practised. It is obvious, however, that the cases in which it will be most successful are those in which the opacity is seated outside of the anterior elastic lamina of the cornea, where it is, in fact, a deposit of lymph in or under the epithelium, to be known usually by its being raised, and prominent from the general convex surface of the membrane. Opacities of the substance of the cornea, as from corneitis, for example, are obviously not amenable to this treatment; and, on the other hand, so far, at least, as our experience goes, they are more frequently cleared away by absorption than the prominent opacities of the outer layer. It is very obvious that an operation of this kind requires a considerable amount of dexterity for its safe execution.

CHRONIC INFLAMMATION AND BLENNORRHEA OF THE LACHRYMAL SAC.

The *Bulletin Général de Thérapeutique* for October contains a paper by M. CHASSAIGNAC, on the treatment of this very common and very intractable disease by injections from the nostril. He recommends a catheter of the form proposed by Gensoul, having, besides the terminal opening, a lateral hole in the convexity, close to the point of the instrument. The fluid is forced by means of a strong syringe into the lachrymal sac, and, on the force with which this injection is made, M. Chassaignac lays much stress.

This is the gist of his paper, disentangled from the usual French verbosity. We have a very strong suspicion that this plan appears better on paper than it will prove in actual practice, inasmuch as the introduction of the lachrymal sound from the nostril is a process very difficult of execution, and very irritating to the subject of the operation. Careful attention to the general health, continued counterirritation over the sac by blistering or nitrate of silver, and, if necessary, the introduction of a style, and injection of the sac and duct from above through the artificial opening, are still, we think, the most trustworthy means of cure.

TRUE OSSIFICATION OF THE LENS AND HYALOID MEMBRANE.

We lately recorded an example of ossification of the vitreous body; another instance of this rare condition of the eye is described by Mr. JOHN KIRK in the *Monthly Journal* for November, and may be well compared with the German case in our last periscope.

A man, aged 50 at his death, and of strumous and syphilitic habit, had lost the sight of his left eye by an injury thirty years before.

The cornea of the right was nebulous, and at some points quite opaque; the deeper structures were not examined.

The left eye was considerably diminished in volume, and of an irregular form; the cornea quite opaque, and marked by numerous cicatrices. The optic nerve was diminished in size. On opening into the posterior chamber, the texture of the sclerotic was found unaltered. The choroid was adherent to a shell of osseous matter occupying the position of the hyaloid membrane. Externally this shell was thin, but up the interior ran a tube continuous posteriorly with the central artery of the retina, while anteriorly it opened against the capsule of the lens. The walls of this tube were very dense, especially behind. The interior was lined by fibrous tissue.

Between this central pillar and the outer wall were numerous spicula of bone. Both the central tube and the spaces between the spicula were filled with masses of cholesterine.

On microscopic examination of the more dense parts, there were found lacunae imbedded in a distinctly fibrous matrix. The

spicula contained numerous well formed lacunae with their branching canaliculi.

The capsule of the lens was quite free from calcareous deposit, although considerably thickened both anteriorly and posteriorly. The lens was smaller than usual, being compressed from before backwards. Both its surfaces were irregular.

The greater part of the lens was intensely hard, but at several points round its margin there remained portions of soft tissue.

On making a section from the margin towards the centre, and examining it with the microscope, the external tissue was found to consist of distinct fibres, arranged parallel to each other. They appeared quite uniform in structure, nor did acetic acid develop nuclei among them. Between these fibres were a number of rounded mineral bodies, becoming more numerous and of larger size as they approached the central mass, near which they often measured one twenty-fifth of a millimetre in diameter. By the mutual contact of such spheroidal bodies, a homogeneous mineral substance was formed.

These masses were of a distinctly crystalline nature, and interspersed among them were a number of well formed crystals, often grouped into masses. Their form seemed to be the rhomb. Both the crystals and crystalline spheroids consisted of a mixture of phosphate and carbonate of lime. The dense central portion of the lens presented lacunae interspersed through its substance, and often arranged in a concentric manner around Haversian canals, which measured a quarter of a millimetre in diameter, and were partially filled up with calcareous matter.

The anterior chamber of the eye was collapsed, and occupied by a small quantity of a membranous matter, appearing to the naked eye very like the loose substance inside a goose quill. Under the microscope it appeared as a clear membrane having a fibrous basis, and quite similar to the elastic layer of the cornea; but on one of its surfaces there were a series of regularly arranged tubercles, which changed their appearance according to the focus. These tubercles appeared in general clear and homogenous, but in many of them a radiating structure could be detected by a careful management of light. This membrane was but little affected by acetic acid.

RHEUMATIC OPHTHALMITIS.

In the *Dublin Quarterly Journal* for November, p. 461 is contained a report by Dr. FRAZER of a case of general inflammation of the eyeball in a young man labouring under cachectic rheumatic fever, complicated with delirium tremens. The onset of the disease was sudden, and its progress very rapid: the patient fell asleep at midnight with his eye free from uneasiness, and by seven o'clock in the morning there was distinct arthritic general ophthalmia; the anterior chamber was quite hazy; the pupil oval and contracted; the iris altered in appearance and colour, and vision very imperfect, though the redness was comparatively slight. The anterior chamber as the inflammation increased, soon filled with lymph, which, however, gradually disappeared under the influence of mercury. In the course of time, all the objective symptoms disappeared, but the eye remained all but quite blind.

From the morbid appearance in this eye, especially the great effusion of lymph, and taken in connexion with the man's "antecedents," we strongly suspected that this was a case of gonorrhoeal rheumatism, and gonorrhoeal iritis.

DISEASES OF THE EAR.

CEREBRAL SYMPTOMS, IN CONNEXION WITH DISEASE OF THE EAR.

This relation of diseases is well known, and we are not sure that in a paper published in the *Canada Medical Journal*, Mr. HENRY HOWARD has materially added to our stock of information on the subject. He gives "four cases of disease of the ear producing cerebral affections, one terminating in death, with remarks." The girl, who died in fits after labouring under otorrhoea, was not inspected, which, considering that such cases are not by any means unusual, might, we think, have induced the author to suppress the record altogether. In the second case there was otorrhoea, with facial palsy, cured under counter-irritation, calomel and quinine, and cod-liver oil. The third case is unimportant; and the fourth we briefly quote:

"M., aged 17, admitted into the Ophthalmic and Aural Ward of St. Patrick's Hospital, November 27th, 1852, stated that for eight weeks she had been suffering with a discharge of matter from her left ear, and that for six weeks it had been accompanied with pain, which had extended to the whole side of her head. She was suffering from giddiness, double vision, and

numbness of the whole of her left side down to her toes. She was quite lame on that side, and could exert but very little power of her arm. All these symptoms had increased for a week before she came to me. The moment I saw her, I observed that there was partial ptosis of the left eyelid. On examining the ear, I found there was suppuration of the middle ear with perforation of the membrana tympani, but I could observe no signs of caries. There was slight tenderness over the upper part of the cervical vertebrae. I put a seton in the back of her neck, ordered her saline purgatives, low diet, and to remain quiet in bed. The next day, on my finding that she had been well purged, I put her upon one grain of calomel and half a grain of quinine three times a day, and had the biniodide of mercury ointment applied behind her ear and to the temple of the affected side. This treatment, with syringing her ear every day with a twenty-grain solution of the sulphate of alum, I continued regularly for ten days, at the expiration of which time the mercurial fœtor was slightly perceptible, and the discharge from the ear ceased. The ptosis, double vision, and giddiness, disappeared, feeling was restored to the left arm, and in a very great degree to the left leg. In walking about the ward of the hospital, very little lameness was observable. A fuller diet was then prescribed. I discontinued the use of the syringe; but to keep up the action of the mercury, I ordered one of the pills to be continued at night. Three days afterwards, the thirteenth in hospital, I was surprised to find her in bed, after having passed a very bad night. Her face was flushed, tongue furred, pulse rapid, with constant twitchings in her left arm and leg. A blister was applied at once to the spine the whole length of the cervical and part of the dorsal vertebrae, the calomel pill was discontinued, and I gave her saline purgatives every four hours, till she was freely purged. Next morning, all these unpleasant symptoms disappeared; I gave her no more medicine. She left me in a week afterwards perfectly well, with the exception of a slight halt or lameness in the left leg, scarcely perceptible to a stranger. I recommended her keeping the seton in for three or four months, and to let me know if she had any return of the disease. A month has passed since, and as I have not heard from her, I presume that she still continues to improve."

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, NOVEMBER 22ND, 1853.

T. A. BARKER, M.D., Vice-President, in the Chair.

PATHOLOGICAL RESEARCHES INTO THE DISEASES OF THE EAR.
BY JOSEPH TOYNBEE, ESQ., AURAL SURGEON TO ST. MARY'S HOSPITAL.

The author gave the results of the fifth series of his researches into the cause of deafness, and presented a list of the appearances shown by *post mortem* examinations of the organs, since the publication of his last paper. He classified his dissections thus:—Ears from deaf persons whose deafness was known, and which had been examined by himself during life, 134; ears from deaf persons, unaccompanied by histories, and not examined during life, 41; ears diseased, but without histories, 226; healthy ears, 207. The author gave a tabular view of the morbid conditions he had seen, referring the more minute description, as regards treatment, etc., to future communications. Further researches had induced him to modify the opinion formerly expressed by him, that deafness seldom depends upon the obstruction of the faucial orifice of the Eustachian tube, inasmuch as a thickened condition of the mucous membrane covering the said orifice is liable to cause obstruction, by preventing the tensor and levator palati from separating the walls of the canal. In many cases of advanced deafness, a diseased condition of the auditory nerve or its expansions was found.

In the sixth series, the author gave in a tabular form the results of the examinations made after death of 1013 diseased ears. The dissections, which were exhibited in a tabular form, were thus classified:—Diseased ears from deaf persons with histories, 136; from deaf persons without histories, 223; from persons without histories, 654; healthy ears, 510; in all, 1523. He mentioned that the existence of a dermoid layer of the tympanum and the general closed condition of the Eustachian tube, have only recently been pointed out. Many important

aural diseases, such as ankylosis of the base of the stapes to the fenestra ovalis, have until now been wholly unknown.

ON INFLAMMATION. BY S. F. STATHAM, ESQ., ASSISTANT SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

The author divided inflammation into sthenic and asthenic. The latter was always due to the presence of a morbid poison, which must be the result of decomposition. The essence of this poison had not been discovered, but its presence was shown by its effects, viz., weakening of the vital forces, increase of the watery secretions, prevention of the formation of fibrin. He remarked its specific effect upon the inflammatory process which it creates and likewise modifies, causing effused plasma to take a less developed form. He described its progress through the body by contiguity, and stated that a special character of the disease consisted in the absence of any prominent local symptom. An account of the phenomena attending pyæmia was given, and the appearances shown by *post mortem* examinations in this disease were described. The author was of opinion that absorption of animal poison was caused by glandular imbibition rather than by venous absorption, and gave the results of experiments on rabbits to prove the correctness of his opinion. He denied the existence of any peculiar odour of the breath accompanying pyæmia. He differed from Dr Jenner as regards the theory of pyæmic fever, stating his opinion that, if the blood had been so polluted as to produce suppuration in an uninjured part of the body, death would have ensued to the patient. General tonic treatment, with local depletion, was recommended as the best under all circumstances.

In the discussion which followed, Messrs. Henry Lee, Erichsen, and Carter, and Drs. Sibson, Schulhof, and Mayo, and the author, took part.

ASSOCIATION INTELLIGENCE.

METROPOLITAN COUNTIES BRANCH:—NOTICE OF SPECIAL MEETING CALLED BY THE COUNCIL.

At a meeting of the Council, held on the 6th instant, it was unanimously resolved that a General Meeting of the Branch should be held at 37, Soho Square, London, on Tuesday, 13th December, at half-past three P.M.

FIRST: To consider what steps ought to be taken with reference to the Vaccination Act.

SECOND: To receive and consider the Report of the Medical Reform Committee.

T. OGIER WARD, *Hon. Secretary.*

COUNCIL PRIZES.

LETTER FROM SIR CHARLES HASTINGS, M.D., D.C.L., PRESIDENT OF THE COUNCIL.

Worcester, December 5th, 1853.

DEAR SIR,—I am anxious, through the pages of the ASSOCIATION JOURNAL, to announce to the members of the Council of the Provincial Medical and Surgical generally, but more especially to those who have subscribed to the Council Fund, that, at the last meeting of the Council at Worcester, the prizes for the best Medical Reports, sent for publication in the PROVINCIAL MEDICAL AND SURGICAL JOURNAL, and also the prize for the best Surgical Reports, sent for publication in the same periodical, were adjudged as follows:—

The prize for the best Medical Reports to Mr. Arthur Oakes, M.R.C.S., late of Queen's Hospital, Birmingham, and now residing in that town.

The prize for the best Surgical Reports to Mr. W. J. Moore, M.R.C.S., formerly of Queen's Hospital, Birmingham, but now in the service of the East India Company.

Feeling desirous that this award should be made public, I beg to request your insertion of this short communication in the next number of our JOURNAL.

Believe me, dear sir, yours truly,

CHARLES HASTINGS,

President of the Council.

To the Editor of the Association Medical Journal.

EDITOR'S LETTER BOX.

MEDICAL STUDENTS.

LETTER FROM FRANCIS DAVIES, ESQ., TO THE EDITOR.

SIR,—I was extremely surprised, and not more surprised than pained, at reading Dr. Golding Bird's letter in the JOURNAL of November 25th.

It appears that there is a systematic attempt being made to convert the medical students as a class into an "organised hypocrisy". I have too high an opinion of their good sense to suppose for an instant that they will be led away by Dr. Bird's saponaceous piety. That there are a sufficient number of Mawworms and Cantwells in the profession, is abundantly proved by the number of signatures obtained to the petition against opening the Crystal Palace on Sundays.

As a class, medical students are the most disinterested, generous, and benevolent, in Her Majesty's dominions; and they would be much better employed in studying John Hunter or Percival Pott, than in Scripture teaching, as there are plenty of active and zealous ministers who would do it much better. I hate, abhor, abominate, and detest, the sneak who would worm himself into a family through the instrumentality of religious tracts.

"O heaven, that such companions thou 'dst unfold;
And put in every honest hand a whip,
To lash the rascals naked through the world."

I am, etc., FRANCIS DAVIES.

Persnore, Nov. 28th, 1853.

[We deeply deplore the tone and spirit of this letter. It was not suggested that medical students should invade the province of the religious teacher, but that they should be led to the too much neglected study of the Bible. It is evident that Mr. Davies must be profoundly ignorant of the results of the Young Men's Christian Association; or he would have paused, ere he ventured to brand an attempt to extend the benefits of such an institution to medical students, as an "organised hypocrisy". The application of opprobrious epithets to the 640 physicians and surgeons of London, the 100 of Edinburgh, in addition to a very large number in the provinces, who signed the petitions against what they conscientiously regarded as Sabbath desecration, needs no comment.—EDITOR.]

MEDICAL STUDENTS.

LETTER TO THE EDITOR.

SIR,—I read Dr. Golding Bird's letter on medical students with great satisfaction. His testimony as to the improvement in their character, as a body, must be admitted; and his conviction that such improvement can be only based on religion, and that the right means to promote medical ethics amongst them is by encouraging more systematic religious training, is both wise and good. Such outspoken convictions of men of established repute in physical science,—men of exact minds, trained in weighing evidence, and not mere speculative writers or solemn dogmatists, have a weight and importance of which they themselves are probably little aware. Such do as much good to those of our profession in strengthening their faith if it is wavering, as homœopathic and Mesmeric, and table-turning clergymen do harm in unsettling it, by destroying all confidence in their judgment. If a man believes that any effect at all can be produced by infinitesimal doses on the body, or that tables talk by signs, or that printed verses may be read when enclosed in hazel-nuts, what will he not believe? says the sceptically inclined student who has been trained to estimate physical evidence. And the same individual, who has been inclined to doubt the evidences of Christianity, has this doubt shaken, by finding that one of his own profession, in the prime of his intellectual faculties, which have been diligently employed in physical and physiological investigations, and in that branch of the practice of medicine on which exact chemical experiments are brought to bear, is himself a firm believer in Christianity.

Having a great regard for our JOURNAL, I felt also glad that we have an organ of our own in which such subjects are admitted, not merely out of sufferance, but because they fall in with the very principles which our Association has so much at heart. I have seen in other journals a sneer at this feature of our own; but this sneer I took as the highest compliment, as a proof that this distinctive characteristic was recognized. Dr. Golding Bird states that twenty years ago a religious student

was ridiculed; now he is respected. And is not the same change apparent generally? Are speeches in parliament, and leaders in the *Times*, ridiculed now because they often recognise the distinctive principles of Christianity as all-important even in politics? but, on the contrary, is not the speaker and the writer respected on the avowal? And so it must be with medical journals, if they would gain respect and character. In its due recognition of the religious element of our nature, the ASSOCIATION JOURNAL is, I feel assured, in accordance with the feelings of a very large and an increasing number of our profession.

I am, etc.,

A MEMBER OF THE COUNCIL.

November, 1853.

MEDICAL STUDENTS.

LETTER FROM A. H. PATERSON, ESQ., TO THE EDITOR.

SIR,—I am very glad to see your columns opened to the discussion of the question of medical education. It would be a great boon to future students, if the Association carefully considered and urged on the profession the necessity of some important changes in the present system.

I have had some experience of the collegiate system, having been, nine and ten years ago, a student at the Queen's College, Birmingham. I do not think that the efforts there made to improve the morals and habits of the students were very successful. Sometimes we had young men so bad that they were expelled; but usually, I am happy to say, the students were industrious and honourable men, who were a credit to the College, and superior to the usual run of provincial students. But the general behaviour of those unconnected with the collegiate establishment, and unaffected by its rules, was at least as good as that of the collegians; and the greater number of prizes was carried off by the out-students, as they were called. Dr. G. Bird's letter appears to be a general testimony in favour of the rapid moral and professional progress of medical students during the last ten years; but how will he answer these discouraging statistics, taken from Mr. Guthrie's lecture published in the *Lancet* of Oct. 8th? He says that, in London alone, in 1850-51, 1,044 students registered, and only 370 obtained their diploma; in 1851-52, 1,141 registered, 404 obtained the diploma; in 1852-53, 1,105 registered, and 476 obtained the diploma. Where are all those young men who never pass the College? These numbers include all who pass, but only those who attend the London schools were registered; so that probably not a fourth of the students in town and country pass the College.

Mr. Guthrie goes on to say, "It has been said that the examinations of the College are more severe of late; but this is a great error; for, if any change has taken place, they are less rather than more severe." "The real fact is, students are worse prepared." Mr. Guthrie was President in 1831-32, and then one in fourteen were referred or rejected. He was again President in 1843, and the number was one in eight; while in last session the rejections were one in six.

I need not follow Mr. Guthrie in his remarks on deficient dissecting, or careless, negligent, or inefficient lecturers; for every one who knows anything of the matter must know that these are patent facts. I have quoted so much to show that Dr. G. Bird is mistaken in saying that "the improved character of the medical education imparted in our hospitals and colleges has not been without its good influence." There is no improvement. The students may not be so openly vicious, but they are more idle and inefficient than ever.

Mr. Guthrie regrets the enforced three years' hospital practice, as he says money is lost, morals deteriorated, and no good result has followed the change from two years. Yet surely three years is little enough.

My own belief is, that no good can be done till the students are relieved from their present incubus of lectures. For three years does the student hear an incomplete sketch of such a science as physiology, read over and over, or some old physician favours a class of two with the practice of physic taught by Cullen. I am speaking of provincial schools, several of which I know; and I can assert that in them the lectures are almost universally repeated from notes year after year without variation; that they are given without spirit by the lecturers and listened to without interest by the students; and that nothing so much tends to make a well disposed youth an idle, drunken, ignorant student, as the necessity of spending four separate and separated hours a day in hanging about a dull lecture room.

Some, and among them Mr. Guthrie, seeing these evils, blame the body of lecturers, as I think unjustly. It is the system that is wrong. Anatomy, physiology, physic and surgery are not

things to be learned by talking, they must be studied. If the staff of lecturers attached to a school were diminished one half; and if a list of the more distinguished, but at present half-occupied young surgeons of the town was kept at the school, and every student was obliged to spend two or three hours daily with some one or another of these gentlemen, and to read on those subjects on which he is now lectured; if one tutor took one subject, and another another, and the student was rigidly obliged to divide his work among them, and undergo a weekly examination on each branch at the college or school, by the professor of that branch—we should I think soon have a different account of the examinations at the College of Surgeons.

I am, etc., ALEX. HENRY PATERSON.

Altrincham, Nov. 28th, 1853.

LORD LYTTTELTON ON HIS VACCINATION ACT: THE WANGFORD UNION.

LETTER FROM W. E. CROWFOOT, Esq., F.R.C.S., TO THE
EDITOR.

SIR,—If you consider the following correspondence on the subject of the Vaccination Extension Act of sufficient importance to interest the profession generally, I shall feel obliged by its insertion in your Journal.

The first portion is an application from the professional men in this town to the Board of Guardians of the Wangford Union, in reply to a notice from them, that they were about to elect a public vaccinator for this district. It is signed by all the legally qualified professional men in the town, except the Union medical officer, who declined to sign it. I regret to add, that he alone was elected to the office.

The second is a letter from Lord Lyttelton, which his Lordship has kindly given me permission to publish, and which may perhaps interest the profession, as showing his Lordship's views upon the subject.

I am pleased to find that several Unions have adopted the plan which we had proposed to the Wangford Union; and I trust that the very partial manner in which the Poor Law Guardians are discharging the trust committed to their care, will lead the legislature to interfere, and compel them to contract with all legally qualified medical men. Such a step would at once tend to conciliate the profession to the Act, and at the same time ensure the most efficient discharge of those important duties for which it provides.

I am, etc., W. E. CROWFOOT.

Beccles, Nov. 22nd, 1853.

"Beccles, 7th Nov. 1853.

"GENTLEMEN,—We beg to acknowledge the receipt of your letter, informing us that you will on the 16th instant proceed to the appointment of Public Vaccinators for the Beccles District of the Wangford Union.

"We feel most anxious, as far as lies in our power, to promote the efficient vaccination of the whole population, and thereby, under the blessing of Divine Providence, to produce the mitigation, if not the total extinction, of the small-pox.

"We find that by the 4th Vict., ch. 20, you are directed to contract with any legally qualified practitioner resident in your district. We would venture to suggest that the most efficient means of accomplishing the object which you have in view, would be attained by electing *all* the qualified practitioners resident in the union to the office of public vaccinators.

"By adopting such a course, you will avoid inflicting an act of injustice upon an honourable profession, which could not fail to be the case, if you appointed a single medical officer, and thereby gave him the opportunity of introducing himself into the practice of his professional brethren.

"We therefore beg to offer ourselves as public vaccinators for this district; and

"Have the honour to remain,
"Your obedient servants,
WM. ED. CROWFOOT,
ROBT. DASHWOOD,
HENRY WM. ROBT. DAVEY.

"To the Board of Guardians of
the Wangford Union."

LORD LYTTTELTON TO MR. CROWFOOT.

"Hawarden by Chester, 11th Nov. 1853,

"SIR,—I only got your letter last night; and entirely am of opinion that the only proper course is for the Boards of Guardians to contract with all the legally qualified practitioners who are willing to do so. It is what has been done in my union

(Bromsgrove); and I should be very glad to hear of its being done everywhere.

"The only limitation we have made is, that it is only the union officers who are allowed to vaccinate at the *outlying stations*, fixed by the authority of the Board; leaving the other surgeons to do so at their own houses, at the houses of the poor, or elsewhere. This is only for convenience.

"Your obedient servant,
"LYTTTELTON."

THE VACCINATION ACT.

LETTER FROM JOHN C. BLOXAM, Esq., TO THE EDITOR.

SIR,—Ruricola expresses himself in the last number of the JOURNAL, in reference to the Vaccination Act, very persuasively and very eloquently; but I wish he had addressed himself more to the *merits* of the Act than he has done. I am by no means sure that the tendency of his letter is not to seduce its readers into a false road. I feel, myself, that the act in question is a first attempt at direct encroachment on private rights. I would say on private property; for the time and professional knowledge of the professional man is to be regarded as property with him, as much as land is with others: and, indeed, in one point of view, this property is entitled to be more respected by the state, *as property*, than that of the landed proprietor; because the landowner is more indebted to the state for his possessions, than the medical man is for his. The latter is in no degree beholden to the state for his property. The state has done nothing, so far as I know, to assist the medical student or practitioner in the acquisition of his property. Railways form one of the necessities of the state, as well as vaccination; but what would Parliament have thought of establishing railways, if it had been proposed to take land for the purpose without leave from the proprietor, and without giving him any equivalent for it? And yet the state is clearly far more entitled to make use of the land of the country than of the professional man's time and knowledge.

Ruricola has very well prepared the way by enlisting one's inclinations on his side. I wish he would now make another step in the same direction, and show that we may follow him, free from any feeling of compunction. I should be glad to find that there is nothing out of the ordinary course of legislation in this Act, and that I might act in accordance with it consistently with a due respect for the independence of myself, as well as of my order, and so I dare say would many others.

I think that Ruricola shows that many medical practitioners took a wrong course prior to the introduction of the Bill; but this does not show that the Act is right. The profession, as a body, is not answerable for the selfish or injudicious conduct of a certain number of individuals—supposing that these terms may be fairly applied to the occasion.

It is the usual, and had been I believe the invariable, practice in this country, to effect desirable national objects, without infringing the rights (I do not say interests) of individuals; and such objects are even abandoned rather than incur a sacrifice in this respect.

I am, etc.,
JOHN C. BLOXAM.

Newport, Isle of Wight, Nov. 16th, 1853.

THE VACCINATION ACT.

LETTER FROM J. H. STALLARD, Esq., TO THE EDITOR.

SIR,—Much has been written concerning the injustice of the New Vaccination Act; and the writers, including the Chief Clerk of the Register Office, unanimously agree that there are no means for providing remuneration for the services required of medical practitioners not specially appointed public vaccinators. I am sure you will admit my reasons for doubting this conclusion. Perhaps the suggestion will lead more qualified persons than myself to see whether I am right. According to Mr. Mann, the duties of the Registrar General are "purely administrative"; in the words of clause 11, he is to provide books, forms, and make "*regulations such as he may deem necessary for carrying into full effect the provisions of the Act.*" And in a subsequent part of the same clause, he is authorised to pay the expenses so incurred. It forms a most important part of his duty to frame such regulations as shall ensure the *full effect* of the Act, and, if necessary, to pay for the same. His payments are *not restricted* to the particular items named in the Act. In his charge will be placed the supervision of the whole, and he will require extra clerks, if not personal increase of salary. He will pay the superintendents of districts for the supervision they

exercise, and for the trouble they will be put to; and he is called upon by the Act to pay for all such services as may be essentially necessary for its public administration. It appears to me that the administration cannot be perfect without the cooperation of the medical profession; which, therefore, he is bound to obtain and pay for. I question if medical men could not claim, under the eleventh clause, remuneration for the certificates they render to the local registrars from the Registrar General.

The practical necessity of having a limited number of public vaccinators appears to me most apparent; nor can it be expected that medical men should be paid for vaccinating their private patients: but this ought not to prevent the medical profession from receiving some public acknowledgement for the duties they perform.

I am, etc.,

J. H. STALLARD.

Leicester, October 31, 1853.

THE VACCINATION ACT.

LETTER FROM C. HOLMES, ESQ., TO THE EDITOR.

SIR,—Clerks of unions and auditors of unions, are not styled "union clerks", or "union auditors"; neither do I think "union surgeons" a correct designation for Poor-law medical officers, inasmuch as they are equally (with few exceptions) private practitioners with those who do not hold such an appointment. It appears to me that the article at p. 865 of the JOURNAL for Oct. 7th, was written with the metropolis in view, and that the essentially provincial character of the Association was overlooked. The simple reason why guardians appoint their officers vaccinators, is that they find the duties better performed by a few officers, than when the same salary is divided amongst many (the very plan you adopt in combining the offices of literary and commercial assistant); and the medical officers accept the appointment, because they can perform the duties with much less labour than another person. That there are some exceptions to this rule, is shown by the letter of H. P., at p. 898 of the JOURNAL.

As my only object is the prosperity of the Association, I trust you will pardon my again troubling you.

I am, etc.,

CHARLES HOLMES.

Chipping Norton, October 18, 1853.

THE VACCINATION ACT.

LETTER FROM E. PARKE, ESQ., TO THE EDITOR.

SIR,—I have read the numerous letters on the Vaccination question, and am of opinion with Mr. West, that Government has no right in common justice to compel private practitioners to deliver, *free of charge*, a duplicate certificate to the registrar. Let the matter then be brought to the test at once; and, if any one is willing to stand fire, I for one will contribute £1 towards defraying his expenses; and should those practitioners who feel aggrieved do the same, we shall soon raise a fund amply sufficient for all purposes; and, if beaten, we shall not die without a struggle.

I am, etc.,

E. PARKE.

West Derby, Liverpool, Nov. 1853.

THE VACCINATION ACT.

SECOND LETTER FROM HENRY TERRY, ESQ., JUN., TO THE EDITOR.

SIR,—I have carefully read the whole of the correspondence in your number of yesterday on the Vaccination Act, and I cannot find anything in it to alter the opinion expressed in my letter, viz., that the chief objection to the Bill consists in the imposing the duty to give certificates "without fee or reward". A "Constant Reader" asks who is to remunerate the vaccinator for that class of patients who have hitherto paid from five shillings to a guinea for the operation? I would say in reply, that there is not a word in the Bill to affect this class of patients; and that *private practitioners*, as heretofore, will continue to be paid for the vaccination of their *private* patients. If I understand the act rightly, in rendering vaccination compulsory, it merely provides gratuitous vaccination for those who would otherwise be liable to the penalty, through inability to pay for themselves. The Registrar's Notice differs materially from that given in Schedule C, inasmuch as it states in plain words that the child is to "be vaccinated either by *your own*" legally qualified medical attendant, or by the "*appointed public vaccinator*". I think this fact very materially affects the operation of the Bill

on private practitioners. On this point I have already had some slight experience, living in a large town in which I do *not* hold any union appointment. Some of my *poorer* patients have already applied to me about vaccination; and if I have found them unable to pay the lowest fee which I was willing to take, I have at once referred them to the public vaccinator. Since my previous letter, a *private patient* of mine, in a village where I am public vaccinator, applied to me for the gratuitous vaccination of her infant. I, of course, expressed my surprise that she should condescend to accept of such a boon (although the fact of so doing, either now or under the old act, by no means implies *pauperism*), but that if she insisted on it, and would bring her infant to the station appointed, I had not the power to refuse. Had this person been the patient of any other medical man, he would doubtless have been greatly offended at me; but in this case, as I have already stated, the new act does not differ from the old one, as in both cases, subject to certain special regulations of individual boards, every parent has a right to gratuitous vaccination.

I am, etc.,

HENRY TERRY, JUN.

Northampton, Oct. 29th, 1853.

THE VACCINATION ACT.

LETTER TO THE EDITOR.

SIR,—Will you permit me to add my most emphatic denunciation to the many that weekly appear in the JOURNAL, on the most unjust, but, I hope, likely to be evaded, provisions of the Vaccination Act.

I am delighted with the tone and spirit pervading some of the communications in your late numbers. I earnestly trust that they will be instrumental in evoking a determined spirit of resistance among private practitioners in every part of the kingdom to which it applies, not only to evade the act to the utmost, as it at present stands; but, as a "Country Surgeon" in your number for October 28th, most properly suggests, to pour in our petitions from every town, village, and hamlet, upon Parliament in the next session, making the noble Home Secretary our principal medium.

If this course were adopted with due spirit and energy, backed by the powerful influence of the Council of the Association, it is impossible that this *furtive* and disgraceful enactment should continue to deface the Statute Book any longer than will be required to modify or repeal it. It is an insult to a noble and too generous profession, and most unworthy of this great and liberal nation.

I trust, Mr. Editor, that a form of petition will be immediately got up by the Council of the Association, and printed in the JOURNAL, with all necessary instructions for putting it into due parliamentary shape for presentation, etc. That being done, I am sure it will be unnecessary to call upon every practitioner, as he values his own dignity, the honour of his profession, and the welfare of his patients, to lose not a moment in giving his best and undivided energies towards the repeal or modification of this most obnoxious Act.

As one instance of the probably unpleasant effects attending the working of the Act, I will relate a circumstance of an union medical officer (*proh pudor!*) who, within this last few days, entered the house of a female patient of mine, who was just recovering from a dangerous attack of peritonitis. More in the spirit of a ruffian than of the harbinger of peace and goodwill, he demanded (in language too unfeeling to be described) whose child the sick woman was nursing? On her telling him that it was her own, and had not been vaccinated, he told her he had come to do it. She remonstrated with him, telling him she had arranged for her own medical adviser to vaccinate it. He threatened to take her child from her, and, *mirabile dictu*, chased this feeble creature round the room for that purpose, until she became faint from fear and exertion!!!

Such is one among the many scenes that have to be enacted under this legal abortion.

Fearing I have trespassed too much upon your indulgence,

I am, etc., A.

November, 1853.

THE VACCINATION ACT.

LETTER FROM S. D. LEES, M.D., F.R.C.P.Ed., TO THE EDITOR.

SIR,—Your last number contains many letters urging that Private Practitioners, having no District appointments, should be permitted to vaccinate at the public expense. The Act is

not intended to supersede private vaccination, nor to prevent the profession getting fees from parties able to pay. To throw it entirely open would abolish vaccination fees in the middle and lower ranks. If the agitation could be confined to obtaining a clause to remunerate the practitioner *for vaccinating poor children he had delivered*, that object would probably be gained in the ensuing session; but, to permit other children (not delivered by the operator) to be vaccinated at the public expense, would confer a privilege upon the private practitioner, at present denied to the public vaccinator, whose appointment is for a limited district only; while the private vaccinator would have no limit. The effects would be, that some practitioners, under plea of vaccination, would be constantly encroaching on the private patients of others. The remedy would be worse than the disease, and cause more ill-feeling in the profession than the present Act. The proper way to meet the new Act, and obtain suitable remuneration, is to make one charge to *include delivery and vaccination*. Then, the parents having *prepaid* the vaccination fee to their own attendant, will not seek the crowded surgery of the public vaccinator. Let every 10s. 6d. case be charged 13s.; guinea cases raised to 1l. 6s., and so on in proportion. Females are so particular in selecting their accoucheurs, that they would cheerfully pay the advance fee rather than apply elsewhere. Those medical gentlemen whose patients would change on account of the trifling additional expense, have so slight a hold on the confidence of their patients, that a codicil to the vaccination Act would not mend their position.

I am, etc.,
S. D. LEES.

Ashton-under-Lyne, Nov. 23rd, 1853.

THE VACCINATION ACT.

LETTER TO THE EDITOR.

SIR,—Allow me to beg insertion, in the pages of the ASSOCIATION JOURNAL, for two or three remarks on the injustice of the Vaccination Extension Act, as it bears on those members of our profession who are not engaged in Union practice.

So much has been already written on the subject, that I shall confine myself to the statement of a single fact, amongst many others, in which I have individually suffered. A patient whom I had attended in two or three confinements, accompanied a young friend to my surgery a few days since. On recognising her, I inquired whether she had not a child for vaccination. The answer she gave, was "that she had received a notice from the district registrar, and had consequently taken her child to the Union surgeon, by whom it had been vaccinated. If she had not received the notice, giving her the option of having her child vaccinated at the public expense, she would have brought it to me, and would willingly have paid me for the operation."

On meeting the registrar the next day, I named the circumstance, the particulars of which he admitted to be correct, and referred me to his printed official instructions, which authorise him to supply the parents of all children, whose birth he registers, with a vaccination notice, but leaving it optional with the parents to take the child to their usual medical attendant, or to the district vaccinator for vaccination.

In the former case, the parents would pay the expense; in the latter, the Union. In the former, I should retain my patient; in the latter I should lose him.

Amongst so large a number of such patients, who abound in a country district, the loss to a non-Union surgeon is considerable, for the majority of persons amongst the humbler classes of society are quick-sighted enough to see their own interest, and thankful enough too for the gift of a vaccination fee, and in no case, except through ignorance, will refuse it. The Union surgeon also will be most ready to accept the case; feeling certain that 1s. 6d. earned in his own surgery, with the certainty of payment, is better than 3s. 6d. or even 5s., when the patient has to be visited three times at his own home, and with more or less uncertainty of recovering his fee.

The injustice to the non-Union surgeon is clearly double. He not only loses his vaccination case, and sees it handed over to the Union-surgeon, in too many cases a mere tyro or adventurer, but has to pay a moiety of the expenses out of his own pocket in the shape of poor's rate.

Trusting that the Legislature will, ere long, see the injustice and dishonesty of the Act, and do all in its power to remedy so flagrant an evil,

I am, etc.,
MEDICUS.

November 15th, 1853.

MILITIA SURGEONS.

LETTER TO THE EDITOR.

SIR,—As unity is strength, so is it necessary for all having an interest in the matter, to bear testimony to the truth of your correspondent's statement as to the inadequate remuneration at present afforded to Militia Surgeons, as published in your Journal of the 18th of this month. Our position is there very accurately portrayed—we are permanent servants performing functions sufficiently onerous, but without any permanent remuneration. I think, with your permission, I can depict even a stronger case; but to do this, it is necessary to enter into a few particulars, which I will do as concisely as possible. For the purpose of supplying the requisite number of men to complete our complement against the last training, and now to fill up the places of defaulters and others, it has been considered necessary by the higher authorities to fix certain days, and certain hours, never less than twice, sometimes as often as four times in the week—for the purpose of the surgeon inspecting and passing recruits. For this service he is paid in the following manner: for the first four recruits 2s. 6d. per head; afterwards he receives the ordinary day's pay of a militia surgeon, amounting to 11s. 4d. For this I have sometimes inspected upwards of twenty men in one day. I ought to add, that if no man is approved of medically, the surgeon receives no pay, though his time has been sacrificed in examining.

The allowance of twopence per head a week for attendance and medicine to all members of the staff, their wives and families, is truly ridiculous; the staff being composed, as your correspondent tells you, of middle aged men, oftentimes with constitutions considerably impaired by service and disease, (for it is only within the last few weeks that applicants for appointment on the permanent staff were ordered to be medically inspected). Accustomed to have a surgeon at hand, to whom they can apply for assistance almost at any time, they do not hesitate to seek his assistance on every trivial occasion—such as those having to pay for advice would certainly not. Moreover there is no provision made for cases of midwifery, so I apprehend we are expected to attend these cases for the same pay; are not all these grievances *justly* to be complained of? Is not this a shameful state of things?

It is not only a feeling that such arrangements cannot long continue, which induces the surgeons to retain their appointments under these adverse circumstances, but, having in many cases been compelled to obtain expensive uniforms, they consider *some* remuneration better than a *decided* loss, which their resignation would entail.

The system of "Poor Law Medical Relief" has been sufficiently long a reproach to this country not to render it desirable that any other government appointment should attempt to vie with it in its insufficient remuneration to medical men, and its general inefficiency.

In conclusion, I would say, let the militia surgeons be up and stirring without loss of time; let them act as you have suggested, petition Parliament themselves as a body, and enlist the sympathies of their brother practitioners against an evil that derogates so greatly from the dignity of the profession.

I am very sanguine that, like those of the long oppressed naval assistant surgeons, the evils complained of will, through the powerful influence of the press, shortly be remedied. I am, etc.,

ONE MOST ZEALOUS IN THE CAUSE.

November 21st, 1853.

MILITIA SURGEONS.

LETTER TO THE EDITOR.

SIR,—I am glad to find that your pen has been taken up in the cause of Militia Surgeons. I was very much pleased with an excellent letter addressed to you in your last number, since which a "circular" has been issued from a committee; and it is much to be hoped that those gentlemen who have taken upon themselves the onerous task and trouble will be cordially supported. They propose a meeting, which is indispensable; and the most central position in England ought to be selected. I for one shall be happy to attend and cooperate with them for redress. Having the honour of holding a commission in the Militia, I am anxious to assist all I can; and if you will permit me to throw out a suggestion, through the medium of your Journal, to my brother officers, I shall feel obliged.

The first question naturally to be asked is, How is our present position to be altered for the best? and through what channel? *All matters connected with staff appointments must go through the colonel of the regiment*: our regulations plainly point this

out. The colonel is bound to forward any memorial to the Lord Lieutenant of the County, who will present it to the authorities, the Secretary of State for the Home Department. It is obvious that by these means our *wants* and *grievances* are better made known. The colonel of a regiment is invariably a gentleman of high birth and distinction, with a great stake in the county where he resides (possibly he may be the Lord Lieutenant, and a member of Parliament). The surgeon is well known to him; and, since "*the training*", the colonel is only too well aware of the onerous duty devolved upon the medical officer of his staff. The Militia will now undoubtedly be a permanent force; for, according to the act of last session, each county is to provide stores, and a building sufficiently large to accommodate *one half* of the permanent staff. The surgeon, as an officer, is as requisite to a regiment as an adjutant. Why, therefore, should he not be attached upon the same half-pay while disembodied? In case of an emergency, the surgeon must go, or be "branded as a coward"; and yet, while all is peace, he is left with an inadequate pay, and in time of tumult is obliged to leave his comfortable snug practice, and risk the war.

I cannot possibly believe, with a true and fair representation, that things will be left as they are at present. Let each medical officer see his colonel, and represent matters to him and the Lord Lieutenant of his county; and I am confident, with "a long pull, a strong pull, and a pull all together", success will attend the redress of the Militia Surgeon. I am, etc.,

ONE OF THE SUFFERERS.

THE INDECENCY OF THE EXHIBITION OF DR. KAHN'S MUSEUM.

LETTER FROM W. B. KESTEVEN, ESQ., TO THE EDITOR.

SIR,—I take the liberty of forwarding for your examination a copy of the catalogue of the wax models now exhibiting at Dr. Kahn's Anatomical Museum, in Regent Street. I have marked certain parts of the catalogue, as containing objects unfit for public gaze. It is true, that the part in which they are to be found, is (professedly) for the inspection of medical men only; but, practically, this is the shallowest pretence. The very restriction, unless enforced, operates merely as a stimulus to prurient curiosity. To my personal knowledge, the restriction exists only on the pages of the catalogue. Accompanied by a medical friend, we were admitted without any question as to our calling; and we there saw persons who, from their audible comments upon the objects before them, were clearly not of the medical profession.

Such an indiscriminate admission of the male public to see wax models of the male and female organs of generation under so many pathological and physiological conditions, I hold to be demoralising; but it becomes a still more grave offence against public morals, when we find that females are admitted to view the same models! Gaudy yellow handbills, distributed to passers-by in the streets, set forth that the exhibition is open on Fridays, to ladies only.

Wishing to know how far females were admitted, I sent a respectable woman (a monthly nurse) to ascertain the point: she returned with the information, that she could have been admitted, on payment of one shilling extra, to that part of the museum which in the catalogue is marked as being exclusively devoted to medical men! but as she had learnt what she went to learn, she did not lay out another shilling upon the additional knowledge.

Such a mockery of restriction as this is too transparent—a shilling extra for admission to the chamber of horrors and indecencies, forsooth, on the only day in the week on which the most inquisitive of mortals are admitted *alone* to this exhibition of anatomical models!

Dr. Kahn has some knowledge of human nature beyond what is got by dissecting and modelling.

I ask your opinion, whether all this does not represent something very like an outrage upon public decency? I cannot believe that an English public will very largely patronise such a disgusting exhibition. I have the fullest confidence in the good taste and delicacy of my countrywomen; and most devoutly do I hope that the time is very far distant when English women shall be content to gain superficial anatomical knowledge, at so great a cost as the sacrifice of their characters for modesty.

I am, etc.,

W. B. KESTEVEN.

Upper Holloway, London, Nov. 9th, 1853.

REVALENTA ARABICA QUACKERY.

LETTER TO THE EDITOR.

SIR,—As one fact has a proverbial superiority over a great many arguments, will you allow me, in connexion with the revalenta pease-meal absurdity, to state the following. It shows how medical men are robbed by the prevailing quackeries of the day.

I was writing a prescription for a poor woman this month, in connexion with one of our medical charities. Looking at her, one would think she was of the ordinary class of paupers. It was a simple case of gastrodynia. As to her paying for medical advice, she thought it cruel to mention such a matter. After she got her medicine, she said that she had been recommended revalenta by a doctor!

"Well," I said, "you tried it, did you?"

"Yes," she replied, "several times; but it does not seem to do much good."

"How many times?" I continued.

"Oh, seven or eight times!"

"And what may have been the size of the last *parcel* you got?" I said jokingly: "the size of that hat?"

"Well," she said with the greatest *sang froid* in the world, "as I live a little at the Clapham side of London, about the size of that hat!"

"And what may it have cost, pray?"

"Oh, only twenty-two shillings! but they send such sweet little books, and all the cures and recommendations of the great chemists."

Only twenty-two shillings! and the woman would not give one farthing for the medical advice we are all spinning our brains to be enabled to give. And yet some of our M.D.'s are so suicidal as to recommend this trash. You are doing good work, sir, along with Dr. Golding Bird, in trying to raise the status of medical men. Try and put down quackery, and every one will bless you.

I am, etc.,

M. D.

Kingsland, London, November 29th, 1853.

CONDITION OF THE FETAL HEAD AT BIRTH.

LETTER FROM GEORGE KING, ESQ., TO THE EDITOR.

SIR,—My paper on "The Condition of the Fœtal Head at the full Period of Gestation" has attracted the notice of Mr. Gaye, who appears to think that there is some ambiguity about it which should be at once explained. In writing for the press, I have always endeavoured to express myself in as clear and simple a manner as possible. If, in stating facts, I have not made myself intelligible in my paper in the JOURNAL for November 4th, I will try to make my assertions clearer; but I must confess I do not see that I have much to explain. However ambiguous my ideas on the subject may be, they seem to have startled Mr. Gaye.

In my explanation of what I believe to have been judicious and orthodox treatment of the cases under consideration, I shall have to reiterate much that I have stated before, as well as to repeat Mr. Gaye's remarks, in order to make us both understood. Mr. Gaye says I have "made a few assertions which are startling, and advises the adoption of a mode of treatment which I cannot but think hazardous. Mr. K. says, 'This high degree of ossification of the cranial bones of the fœtus, I believe, more frequently renders the operation of craniotomy and destruction of the child necessary, than does contraction or deformity of the pelvis.' And again, 'Instead of the fœtal head being found fixed or resting on the brim of the pelvis, as is to be found in all illustrated representations of this operation, we should find it moveable, and, the moment we touch it with a perforator, it recedes, etc.' The first quotation is an assumption requiring confirmation." This opinion is formed from practical observation: the confirmation must depend on the experience of others. "As regards the second, I imagine few men would be inclined to craniotomise until the head of the fœtus was firm against or impacted in the brim of the pelvis." Mr. Gaye must bear in mind that my remarks refer to the large highly ossified fœtal head, incapable of becoming fixed, possessing no adaptability to mould itself to the pelvic outlet; and if there had not been much liquor amnii discharged, the uterus would be still buoyant, and would rend with the slightest touch when the pains were off. In these cases, the only treatment is the reduction of the size of the fœtal head. If a practitioner did not feel inclined to craniotomise until the head of the fœtus was firm against or impacted in the brim of

the pelvis, he must expect by his patience to lose his patient; for the head would never yield to the uterine action. Mr. Gaye says, "The next paragraph is odd. 'I have never heard the child cry *in utero*;' but I have heard one make a frightful noise after the head has been broken down, and the brains smashed by the operation of craniotomy, while the body was still lying in the passage. Fortunately, the bed clothes drowned the sound; but it produced such a very peculiar sensation on the tympanum of my ears, and the gentleman that was with me, that neither of us will ever forget it." May I, with all due submission, ask Mr. King what is meant by the foregoing? Does Mr. King wish to give to the profession as an original discovery, that, although he does not assert that a child cannot cry *in utero*, yet, with a broken head and a smashed brain, a fœtus can give utterance to a frightful noise? I must confess I do not quite understand this question. Mr. Gaye must know that, the moment the air rushes into the lungs, the vocal organs may be put in motion, and we have a cry; and I believe that it is quite possible that it may pass through the vaginal passage; and should the presentation be favourable, with the cavity of the chest of a fœtus *in utero*, by which the action of the lungs may be excited, and the vocal organs set in motion, so that a cry might have been heard from that quarter. If Mr. Gaye will take the trouble to look, he will find a case recorded. Surely there can be nothing very odd in my telling the readers of the Journal that I never heard a child cry in such a situation. Without my enlarging on the physiology of the voice, Mr. Gaye will excuse my telling him that the brain has but little to do with it; and it is quite possible that air may find its way into the lungs of a child in its passage into the world; although its cranial bones may have been crushed, and its brains dreadfully mutilated, it may still be alive, to give utterance to a frightful noise. I cannot conceive that there is anything "odd" in my stating that such a thing did occur.

"Again, does Mr. King wish to assert, that the use of the stethoscope, to ascertain the life or death of the child, is awful practice, and trifling with a valuable life intrusted to one's care?" I have stated that I consider, in cases where there is a high degree of ossification of the fœtal head, the child *in utero* would be likely to retain the vital spark longer than the maternal constitution would hold out; therefore, to be waiting for stethoscopic diagnosis, and listening with the stethoscope till the mother became "an inert and lifeless mass", would be, in my opinion, awful practice, and trifling with a valuable life intrusted to one's care.

The next question is a very simple one. "Must we plunge our fingers into the vagina, run the tips of them against a high degree of ossification, and as quickly let the perforator take the place of the finger?" No: before you let the perforator take the place of the fingers, it will be necessary that the fingers should be got beyond the vaginal passage into the cavity of the pelvis; and very often more than the tips will be required above the brim, before the perforator is to take their place. Depend on it, an educated finger will be of much more service in these cases than a stethoscopic ear. I have no notes of the thickness of the calvarium; but I know I could not discover the sutures.

I have now only to notice Mr. Gaye's last paragraph. "In the case Mr. King refers to, of the head having been fractured at birth, the fracture, I should have imagined, was the natural result of a child's head coming into violent contact with a hard floor." Many an osseo-cartilaginous fœtal head has come into violent contact with a hard floor, without being fractured. I believe no fœtal head would be fractured under the circumstances I have mentioned, unless it was in a *high degree ossified*.

I am, etc.,

GEO. KING.

Bath, Nov. 29th, 1853.

NITRATE OF SILVER STAINS.

LETTER TO THE EDITOR.

SIR,—Allow me, through the medium of your JOURNAL, to introduce to the members of the profession a remedy for the unsightly stains of nitrate of silver. The cyanide of potassium, in a solution of the strength of fifteen grains to an ounce of distilled water, gently rubbed upon the stain, will be found to eradicate it almost immediately.

I am, etc.,

W. C.

York, November 22nd, 1853.

GRATUITOUS MEDICAL ADVICE.

LETTER FROM SIR JOHN FORBES, M.D., TO THE EDITOR.

SIR,—I have been for some time intending to address to you a few words on a subject which has obviously engaged a good deal of your attention of late,—I mean the subject of Gratuitous Medical Advice; and I now find that I have delayed my communication until I have been anticipated in much that I had to say, by the letters in your last number, and especially by the admirable letter of Dr. John Barclay. I still, however, hope that you will indulge me, as an old member of the Association, so far as to give me space enough in your pages for the declaration of my individual opinion on a subject which must interest not only every member of that society, but every member of the profession. Even were I to go over precisely the same ground as your able correspondents, I think I might be forgiven, since the subject is sufficiently important to bear even a superfluity of discussion.

It has not been without pain that I have noticed in more than one of your late comments on the subject of Gratuitous Medical Advice, expressions which seemed to me too much in harmony with the hard, utilitarian, tradesmanlike maxims, which, from another source, have, for many years, been tending to lower the tone of generous feeling, and the sense of honour and dignity in the members of our profession. I am willing to hope that in so interpreting your words I may have been misled by an over-sensitiveness on my part; and the rather, because I should feel it difficult to reconcile such a leaning on your part, with your duty to the Association, which has declared "maintenance of the honour and respectability of the profession" to be one of its fundamental objects.

I do not mean to deny that the practice of gratuitous advice has been abused both by the givers and receivers; as what category of mere human dealings is free from error? But I would ask, Is there no abuse on the other side? Have not humanity and the dignity of the medical character been outraged, in an infinitely greater degree, by the monstrous pecuniary charges made by medical men for services to those who *had a right* to claim their aid as members of the noblest and most benevolent of professions? Neither do I say that the existing abuses in the modes of gratuitous relief ought not to be corrected when discovered; but while dealing with the evil, let us beware lest we incur the danger of tampering with the good. It is one thing to free our professional ground from weeds, and another thing to uproot any of the fruits of the seed sown in it by our noble and high-minded predecessors.

My fear, I confess, is, that, in the present crusade against imposition and unfair claims on the part of patients, we may run the risk of doing irreparable injury to the class of men on whom the unfair claims are made; that, in seeking to get rid of what is, at most, but an extrinsic and superficial evil, we may peril what is of the very heart and essence of our professional calling. It has ever been the proud and just boast of the medical profession, that its members do more good to their fellow creatures, without pecuniary remuneration, than the members of any other profession; and God forbid that the day should come when it could make that boast no longer. Better, I say—a thousand-fold better—that we should be all, now and then, imposed on, in having our sympathies falsely excited, and our time unnecessarily engaged (it cannot be *wasted* in such a service), by a few mean men who filch the benefit they ought to pay for—than that we should shut our doors or our hearts against the thousands of the poor and needy who, most unquestionably, *have a claim* for aid from us, both as men and physicians.

And what, after all, is the mighty sacrifice we make, in responding to this appeal of brotherhood, even when the appeal is unwarranted? What, but the giving up of a few minutes of our time (often otherwise unemployed) to the exercise of the very art in which is our delight? If this sacrifice were one altogether unalloyed by any resulting good to ourselves, it surely could only be regarded as slight and insignificant; and when it is accompanied, as it always must be, by the gift of *experience* to the young (as so well stated by Dr. Barclay), and by the consciousness to all of good done to another—be that other deserving it or not—surely the deed must change its name of *sacrifice* to that of *privilege*.

I cannot close this note without a passing reference to that paragraph in your last leader, in which you sneer at physicians who afford gratuitous advice to certain classes of persons whose education and position in society give them the feelings of gentlemen and gentlewomen, but whose limited means incapacitate them, without great personal sacrifices, for the payment of either the "fees" of the physician or the "bills" of the general practi-

tioner. Surely, while penning that paragraph, you must have forgotten some of the most precious lessons in medical ethics handed down to us by our venerable masters and foregoers, else you would never have treated the matter as you have there done. You cannot be ignorant that it was the invariable practice of the physicians of former days, and has still been that of those who, like myself, have been brought up in the old school, to hold as exempt from fee-giving nearly all the classes enumerated by you in that paragraph; and that the practice of the old school is yet, happily, the rule of many of the rising generation. I need no further evidence than the noble letter of my young friend Dr. John Barclay. Heaven forbid that this old fashion, at least, should ever cease to be the mode among British physicians! Allow me to add, that the application by you of the epithet "erotic" to the conduct of gentlemen whose kind feelings may have prompted them to decline fees from poor gentlewomen, whatever might be their worldly position, is not merely ungenerous, but offensive; and I am sure, on referring to the paragraph containing it, you will regret having used the word, and be ready to admit, with me, that even the HOMER of the ASSOCIATION sometimes nods in marshalling his letters in the field.

I am, etc.,

JOHN FORBES.

Old Burlington Street, Dec. 6th, 1853.

[We stated in our last number (p. 1047), that we conceived it to be now our duty to leave the subject of Gratuitous Services in the hands of the Committee of inquiry, as every member of the Association was invited to lay his views before it. We said: "It is not our intention, either by a notice of communications or otherwise, to anticipate a discussion which can only properly arise after a report has been furnished." We certainly had intended not only to cease from discussing the subject ourselves, but also, in the mean time, to close the Journal against letters on the subject. We feel assured, however, that we best perform our duty by making an exception from the rule which we had laid down, to the extent of printing, without comment or reply, the letter of Sir John Forbes. Our aim, in this and all other discussions which arise in the Journal, is to avoid pushing our individual views in a controversial spirit, and, at the same time, to hazard with frankness our own opinions, so as effectively to elicit the sense of the profession. We have spoken; and it is for others to say whether Sir John Forbes has correctly interpreted and fairly judged our sentiments. EDITOR.]

NEWS AND TOPICS OF THE DAY.

CLOSING OF METROPOLITAN BURIAL GROUNDS. By orders in Council, dated the 25th of November, which appeared in Tuesday's *Gazette*, burials must be wholly discontinued from the 6th of December in the parishes of St. Botolph, Billingsgate, and St. George, Botolph Lane; in the church-yards of the parishes of St. Mildred-the-Virgin and St. Mary Colechurch; in the parishes of St. Martin Outwich and of Allhallows-on-the-Wall; in the burial-grounds of St. Michael Bassishaw and Christchurch, Newgate Street, with St. Leonard, Foster Lane; in the churchyard and vaults of St. John, Wapping; in Sheen's New Burial-ground, Whitechapel, in which burials have already taken place; in the London Hospital burial-ground; in the vaults under Holy Trinity, Southwark; in New Bunhill Fields Cemetery, in the part already buried in; in the vaults under the Wesleyan Chapel, Deverell Street; in the City Bunhill Fields burial-ground; in St. Mary, Battersea; in All Souls, Fulham, in that part in which burials have taken place within the last 20 years; in St. Mary, North End, except under certain restrictions; in the Dutch Reformed Church, Austinfriars; in St. Barnabas, Kensington; in the Neckinger burial-ground; in Southwark Chapel and ground; in St. John's, Clerkenwell; in Benjamin Street burial-ground; under Greenwich Road Chapel; under St. Mary, Rotherhithe; in Christchurch, Rotherhithe; in Stepney Meeting burial-ground; in St. John's New burial-ground, Horselydown; under St. Anne's, Limehouse; in Salem Chapel burial-ground; in Enon Chapel burial-ground; under Queen Street Chapel, in St. Anne's, Limehouse; in St. Peter-ad-Vincula; in Old Gravel Lane Chapel burial-ground, in Gibraltar burial-ground; in and under St. Nicholas, Deptford; under St. Paul, Deptford; in and under High Street Chapel; in and under the Wesleyan Chapel, Mary Ann's Buildings; in the Quaker burial-ground; in the General Baptist burial-ground, Church Street; under Holy Trinity, Brompton; in Stockwell

New Chapel burial-ground; in the burial ground of and under the City Road Chapel; in Bunhill Fields burial-ground; under St. Mary's, Stratford-le-Bow; in the East London Cemetery, and under Brunswick Chapel, Stepney; in East Hill burial-ground, Wandsworth; in the ground and under the Roman Catholic Chapel, Moorfields; and in Putney parish church. It is further ordered that burials be discontinued in the churchyard of St. Peter's, Hammersmith, at the end of twelve months; in the churchyard of All Saints, Poplar; of the Roman Catholic burial-ground, Wade Street; in Sheen's burial-ground wholly, and in various other grounds enumerated on the 1st of April next year. Other burial places will be closed within various periods in this and in the ensuing year. Burials in All Souls Roman Catholic Cemetery must be discontinued within five years, and restrictions are placed on the burial of more than one body in one grave in the great majority of those burial-grounds which are allowed to exist in future, the rights of family burial in private graves and vaults being, however, in several instances preserved.

ROYAL SOCIETY. The anniversary of this society was held November 30th, the Earl of Rosse, president, in the chair. His Lordship delivered his annual address; after which the Copley medal was presented to M. Dove, of Berlin, for his work on the distribution of heat over the surface of the earth; and the Royal medal to Mr. Charles Darwin, the eminent naturalist, for his works on natural history and geology. The following office-bearers were elected for the ensuing year. *President*, the Earl of Rosse; *Treasurer*, Colonel E. Sabine; *Secretaries*, S. H. Christie, Esq., and W. Sharpey, M.D.; *Foreign Secretary*, Rear-Admiral W. H. Smyth. *Other Members of Council*, T. Bell, Esq., Rev. J. Booth, LL.D., *W. de la Rue, Esq., *Captain Robert Fitzroy, R.N.; T. Graham, Esq., *W. R. Grove, Esq., J. D. Hooker, M.D., *T. H. Huxley, Esq., H. B. Jones, M.D., G. Newport, Esq., *J. Phillips, Esq., *Sir F. Pollock, *Rev. Baden Powell, *G. G. Stokes, Esq., *W. Tia, Esq., *Charles Whetstone, Esq.

Those names to which an asterisk is prefixed are those of new members of Council.

After the meeting, the Fellows of the Society and their friends dined together, at the Freemasons' Tavern, the Earl of Rosse, President, in the chair.

LIBELLOUS STATEMENTS REGARDING DR. W. O'CONNOR. [Bail Court, Nov. 25. The Queen v. O'Shea and others.] Mr. Sergeant Shee moved for a rule to show cause why a criminal information should not be filed, at the instance of Dr. William O'Connor, against Michael Keating O'Shea, Thomas Clayton, the elder, and Thomas Clayton, the younger, for a libel which appeared in a paper called the *Weekly Telegraph*, published in Dublin. The libel contained statements that the applicant was not entitled to put "M.D." at the end of his name, and imputed, generally, that he was an impostor. The affidavits denied all the imputations in the libel, and stated that, in October 1852, the applicant was examined for three days before the University of St. Andrew's, in Scotland, as a candidate for the degree of M.D.; and that, after such examination, he had been declared to have passed his examination, and he received the degree of M.D.; and the applicant denied that he was a samter about the House of Commons, as imputed in the libel, while he admitted that he occasionally went there to see members. Mr. Justice Crompton said he thought the article libellous; and remarked, that perhaps the object would be attained by publicity. Rule granted.

FEVER STATISTICS OF THE FRENCH GARRISON AT ROME. In a Roman newspaper of the 20th October, we find the following paragraph:—"The influence of fever, which has been more than usually severe this season, is now on the decline. The medical returns of the French garrison for the months of July, August, and September, show the following results:—

Patients in hospital at 1st July	179
Patients admitted during July, Aug., and Sept.	343
Patients dismissed during same period	259
Patients died during same period	45
Remaining in hospital, 30th September	138

The mortality has therefore been three per cent. This result is the more satisfactory, because among the 45 deaths was one suicide, and some chronic cases of phthisis and disease of the heart, as well as some cases of typhoid fever among soldiers recently arrived from France. The deaths from the Roman fever were therefore very few. The cases, though of the same character, were not nearly so severe as those which prevailed among the French troops in Africa."

MEDICAL SOCIETY OF LONDON. The following papers are announced.

Saturday, December 10th. The Modern Philosophy of Cancer. By R. Druitt, M.D.

Monday, December 12th, in the Physiological Section. The Modus Operandi of Narcotico-Irritants. By John Snow, M.D.

Saturday, December 17th. Source of Hemorrhage in Partial Separation of the Placenta. By F. W. Mackenzie, M.D.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH. At the Annual Election Meeting of the College, held on the 1st December, 1853, the following gentlemen were chosen Office-Bearers for the ensuing year:—*President*: Dr. T. S. Traill. *Vice-President*: Dr. James Y. Simpson. *Other Members of Council*: Dr. Robert Christison, Dr. Alexander Wood, Dr. John G. M. Burt, Dr. James Begbie, Dr. John Taylor. *Censors*: Dr. John Hughes Bennett, Dr. David MacLagan. *Treasurer*: Dr. John Taylor. *Secretary*: Dr. Alexander Wood. *Librarian*: Dr. John Brown. *Procurator-Fiscal*: Dr. John Moir. *Keeper of Museum*: Dr. James Stark. *Clerk*: Mr. Kenneth Mackenzie. *Under-Librarian*: Mr. John Small. *Officer*: Thomas Marshall. *Examiners of Foreign Graduates*: Dr. Robert Christison, Dr. T. S. Traill, Dr. Wm. Seller, Dr. John Moir, Dr. Alexander Wood, Dr. William Robertson, Dr. David MacLagan.

UNIVERSITY OF LONDON:—PASS LIST. M.B. Second Examination, 1853. *First Division*:—Henry Briggs, University College; Erlin Clarke, King's College; James Cato De Castro, University College; James Ekin, University College; Evan Evans, University College; John Henry Gould, University College; William Edward Masfen, King's College; William Roberts, University College; John West Walker, St. Bartholomew's Hospital; Thomas Buchanan Washbourn, Guy's Hospital.

ROYAL COLLEGE OF SURGEONS:—PASS LIST. The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the college at the meeting of the Court of Examiners, on the 18th November:—Messrs. Frederick Bromley, Bath; Edward Hemings Snoad, Ashford, Kent; Walter Leach, Martock, Somerset; Edward George, Calcutta; Edward Long, Berkeley, Gloucestershire; Frederick Edgar Cockell, Queen's Road, Dalston; John Maurice, Plymouth; John Birch, Manchester; Charles John White, Storey's Gate, Westminster; John Bishop King, Brighton; and Robert Harmer, Wells, Norfolk.

At the same meeting of the Court, Mr. William Patrick passed his examination for Naval Surgeon.

LICENTIATES IN MIDWIFERY admitted:—James Lovell, Canterbury, diploma of membership dated June 17th, 1853; Charles Dunn, Scarborough, July 4th, 1853; John West Walker, Spilsby, October 11th, 1850; Samuel Argent, Hinchley, July 1st, 1853; John Rains, Bonsall, Derbyshire, May 20th, 1853; Thomas Duncan, Chelsea, October 28th, 1853; John Hudson, Newport, Yorkshire, April 15th, 1853; Henry Thomas Cornelius, Northampton, July 9th, 1850; Thomas Joseph Cookson Powell, Bristol, October 28th, 1853; Frank Powell, Chichester, October 14th, 1853.

APOTHECARIES' HALL:—PASS LIST. Thursday, Nov. 3rd, 1853:—William Valentine Bird, Seacombe, Liverpool; Thomas Booth Brierley, Tattenhall, Cheshire; John Wells Fletcher, Upton-on-Severn, Worcestershire; George Augustus Fulcher; Robert Harmer, Wells, Norfolk; Henry Frederick Marley, Padstow, Cornwall; John Benson Pritchard, York; Silvanus Tucker, Bridport, Dorsetshire.

Thursday, November 10th:—William Boyd Moss; Augustus Charles Short; William Armstrong Smith, Bedford; William Stillman, Camp Hill, Birmingham; William Williams Thomas, Fishguard, Pembrokeshire.

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

BURD, Henry Edward, Esq., elected Surgeon Extraordinary to the Salop Infirmary, Shrewsbury.

HALDANE, Daniel Rutherford, M.D., appointed Pathologist to the Royal Infirmary of Edinburgh, in the room of Dr. W. T. Gairdner.

*KIRKMAN, William P., Esq., Assistant Medical Officer to the Suffolk County Asylum, elected Assistant Medical Officer to the Devon County Lunatic Asylum, in the room of Dr. John Manley.

*LEONARD, Crosby, Esq., elected Surgeon Accoucheur to the Bristol Dispensary on the 11th November, in room of W. James, Esq., deceased.

*WOOD, Samuel, Esq., elected Surgeon to the Salop Infirmary, in the room of H. E. Burd, Esq., resigned.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.]

*FOOKES, Robert, Esq., of Stalbridge, Dorset, at 49, Cumberland Street, London, aged 52, on December 1.

FRITH, Richard, M.D., late of the Bombay Medical Establishment, at Counter Hill Villa, Lewisham Road, aged 63, on November 22.

SINGLETON, Joseph W., Esq., Surgeon, at Hill Top House, Leicestershire, on November 12.

THATCHER, John, M.D., at 14, Picardy Place, Edinburgh, on November 30. Dr. Thatcher graduated at Edinburgh in 1805; and in 1816, he commenced to deliver lectures on Midwifery and Diseases of Women and Children. He gradually acquired, and for a long time possessed, a large share of the confidence of the public. Increasing infirmities have for some time past greatly withdrawn him from practice.

WOODWARD, Thomas Charles, Esq., Surgeon, of Penton, near Andover, aged 59, on November 7.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. L.

LONDON: FRIDAY EVENING, DECEMBER 16, 1853.

NEW SERIES.

INSTRUMENTS FOR MEDICO-METEOROLOGICAL OBSERVATIONS.

IN reply to several queries respecting the best instruments for medico-meteorological observations, we are now able to offer a few remarks, which we hope will be found useful.

The following instruments may be safely recommended:—Barometer, by Barrow, 26 Oxendon Street, London; Dry and Wet Bulb Thermometers, Maximum and Minimum Thermometers, Rain Gauge, by Negretti and Zambra, 11 Hatton Garden, London.

Excellent, but more expensive instruments, by other eminent makers, might be named; but, as a *set* for the use of meteorological observers, the above will be found complete. The whole are made under the direction of JAMES GLAISHER, Esq., F.R.S., who compares their readings with the standards of the Royal Society, and gives a certificate to that effect, containing the index errors of each instrument. This is most important and essential, as no observations can be relied upon without these errors having been ascertained.

With regard to fixing the instruments, and taking observations:—

Before fixing the barometer, incline it a little downwards, so as to allow the mercury to reach the top of the tube. If the “tap” of the mercury be heard distinctly, the vacuum is perfect; but if the sound be dull and “puffy”, the vacuum is imperfect. Fix the instrument in a good light, so that the ivory point in the cistern, and the top of the mercurial column, can be clearly seen. It must be placed perpendicularly, which can be done by applying the line and plummet sideways and in front; and, if not quite perpendicular when fixed, it can be made so by the adjusting screws at the top of the stem. On reading the instrument, first write down the reading of the attached thermometer; then tap the wooden frame; next, by means of the screw at the bottom of the cistern, put the surface of the mercury so near to the ivory point as to show it and its reflection *just* in contact. Set the index to the upper surface of the mercurial column, just near enough to exclude the light, placing the eye so as to bring the lower edges of the index to coincidence.

The dry and the wet bulb thermometers should be fixed in a shaded place, where the air can have free access. The wet bulb is kept moist by being covered with book-muslin, having in contact with it lamp-wick, which communicates with a small vessel of rain-water. A full description of these instruments will be found in Glaisher's *Hygrometrical Tables*, which may be procured from Messrs. Taylor, of Bolt Court, London.

In fixing the maximum and minimum thermometers, the place chosen must be perfectly shaded from direct sunshine, and protected from rain and local radiation. They should be so fastened as to allow one end to be detached, for the purpose of adjusting the indices.

The thermometer for solar radiation should have a black-

ened bulb, be freely exposed to the sun, and so placed as to be free from any object heated by the sun's rays.

The thermometer on grass should be placed in an open space, freely exposed to the sky, where there are no trees, hedges, walls, or any object that might prevent free radiation.

In reading the thermometers, the observer should avoid breathing upon them, or in any way warming them by the too near approach of his person. It is necessary, therefore, to take the observations *quickly*.

The mode of measuring the quantity of rain will depend upon the construction of the rain gauge in use.

The observer should have access to some trustworthy wind-vane. He must ascertain, by means of a compass, whether the cardinal points are correctly arranged; bearing in mind the number of degrees of declination from the astronomical meridian of the locality.

Certain corrections for capillarity and temperature have to be applied to the barometric observations, which may be ascertained by referring to pp. 81, *et sequent*, of the *Report of the Committee of Physics*, published by Richard and John E. Taylor, Red Lion Court, Fleet Street, London.

The several facts to be deduced from the readings of the dry and the wet bulb thermometers, such as the temperature of the dew point, the elastic force of vapour, the weight of vapour in a cubic foot of air, the degree of humidity, etc., must be done from Glaisher's “Tables”, before mentioned.

We have reasons for believing that the few remarks we have now given will be acceptable to several gentlemen. It is not unlikely, however, that some difficulties will be met with; and some questions may arise requiring solution, particularly in reference to the use of the “Tables” before named. We have no doubt that any of the gentlemen, whose daily observations are inserted in this Journal, will be most happy to afford any information which may be required: indeed, we are already authorised to say, that two of our coadjutors, Dr. MOFFAT of Hawarden, and Dr. BARKER of Bedford, will be glad to answer, in the mean time, any questions addressed to them.

THE MEDICAL REFORM MOVEMENT.

AFTER a brief repose, the subject of MEDICAL REFORM has once more come into the arena of public discussion, as will be seen by the report in another page, of the proceedings of the Metropolitan Counties Branch. It is probable and desirable that all the Branches will, at their earliest convenience, meet to consider the draft of the Bill sanctioned by the Reform Committee, and which is likely soon to be published in the Journal. With this document in view, subsequent debates are likely to take such a turn as will cause them to elicit and impart more information regarding details, negotiations, and concessions than transpired on Tuesday.

The present position of the Draft Bill of the Medical Reform Committee of the ASSOCIATION ought to be borne in mind. It may be stated in a very few words.

The last published edition of the Bill came out on the 10th November, 1852; but the Committee did not then pledge themselves to every detail of the Bill, though they expressed their conviction that its general principles commanded the assent of the great majority of the profession. On the contrary, they solicited comment upon it from the different corporate bodies, and from the different classes of practitioners; and they avowed their wish and their determination to bring it as much as possible into harmony with the general sense of the profession, whilst they kept steadily in view the three principles to which the ASSOCIATION has been so long pledged: viz.

I. UNIFORMITY OF QUALIFICATION.

II. EQUAL RIGHT TO PRACTISE THROUGHOUT THE KINGDOM; AND

III. REPRESENTATIVE COUNCILS FOR THE GOVERNANCE OF THE PROFESSION.

The Reform Committee has been in friendly communication with the Scottish Colleges, and with the College of Physicians in London. They have also received hints and advice from several Branches of the ASSOCIATION. It is the result of all these negotiations and correspondences which is to be considered by the Committee on Monday next at Birmingham. At that meeting, we believe the draft of a Medical Reform Bill will be agreed to, and forwarded to us for immediate publication. We trust that the Committee may continue to receive general support, and that funds may not be wanting to enable them to make the coming campaign one of vigour and of victory. The donations already received are considerable, and the pecuniary assistance announced by Sir Charles Hastings as having been contributed by the Gloucestershire Association is a peculiarly encouraging sign of confidence and co-operation. We trust that all minor differences may be merged, and that a united and energetic demand may be made for such a measure as all will be ready to admit is at least a good instalment of Reform.

If the general sense of the meeting of the Metropolitan Counties Branch be in accordance with the feeling of the profession throughout the kingdom, two things are evident. FIRST, that the silence for some months past must not be taken as an indication of apathy on the part of medical men on the question of medical reform; and, SECONDLY, that the *principle of representation*, more or less extended, must be admitted in a reform bill calculated to satisfy the profession.

During the discussion, a collateral question of great interest and importance was incidentally, though plainly, referred to by Dr. Webster, Mr. Bowling, and Mr. Richardson, viz., the adoption of the representative principle in the constitution of the General Council of our own body. Two of these gentlemen, Dr. Webster and Mr. Bowling, are known and respected as veteran reformers and enlightened practitioners; while Mr. Richardson is a junior member of the ASSOCIATION, and more the man of science than the politician. It would be out of place here to enlarge upon this question; but it would be equally wrong to allow the observations of the gentlemen referred to to pass unnoticed, believing as we do that they refer to a question upon the judicious solution of which depends much of the life, usefulness, and future greatness of our ASSOCIATION.

We ought not to conclude this notice of the meeting of Tuesday, without again reminding our readers, that as the new edition of the Bill is not yet promulgated, the proposi-

tions discussed were of a general kind, and reflected merely the opinions of the gentlemen present upon abstract principles of medical reform. Those who wish for additional information as to the operations of the Committee, or who desire to make donations to its funds, ought to place themselves in communication with its Secretary, G. W. Hastings, Esq., 6, Paper Buildings, Temple.

TO CORRESPONDENTS.

CHOLERA. Letters postponed in consequence of the unexpected length of the Reports of the Edinburgh Medico-Chirurgical Society and Metropolitan Counties Branch.

MEDICAL STUDENTS. We have received a great many letters on this subject. They shall have our earliest possible attention.

NEWS AND TOPICS OF THE DAY.

THE MEDICAL PRACTITIONERS OF THE CHORLTON ON MEDLOCK UNION AND THE VACCINATION ACT. The following memorial to the Poor Law Board, and to the Board of Guardians of the Chorlton Union, was unanimously adopted at a meeting of the profession residing in the before named Union, held on Tuesday, December 6th; Dr. Bowman occupying the chair. The signatures are forty-three in number, constituting six-sevenths of the whole profession within the Union, exclusive of the present district vaccinators.

"To the Honourable the Commissioners of the Poor of England and Wales, the memorial of the undersigned medical practitioners, resident within the limits of the Chorlton Union, respectfully sheweth,—That experience has already demonstrated the Compulsory Vaccination Act to be an inefficient measure, since, whilst it requires medical practitioners to furnish duplicate certificates of successful vaccination, it contains no provision for their remuneration for the trouble such certificates must occasion. Neither has the Act any power to enforce the production of these duplicates; this object being only attainable by an indictment for misdemeanor. The adoption of this course would render the measure still more odious both to the profession and to the public, and would further tend to defeat the objects contemplated by its promoters. That, in the opinion of your memorialists, all the purposes of the Act would be attained by appointing each qualified practitioner a vaccinator, and by paying him for every duplicate certificate of successful vaccination. That, whilst the adoption of this plan would encourage the younger practitioners to vaccinate the children of the poor, it would, by its recognition of the just claim of the profession to remuneration for its labours, lead all classes of its members to co-operate heartily in giving effect to the Act, and thus make the practice of vaccination universal.—E. Tomlinson, William Skinner, Wm. Winn, Farquhar Milne, Thomas Mellor, A. T. Preston, J. W. Wainwright, John D. Ward, Thomas Wild, James Armstrong, Peter N. Roberts, Thomas J. Wilkinson, J. Robb, Robert Hislop, Samuel Whillow, Joseph McKend, Hector Helsham, W. C. Williamson, R. Trafford Whitehead, James Lowe, St. John Wells Lucas, John Dill, Geo. Pettinger, Geo. Wm. Pettinger, H. M. Williamson, J. Wilson, James E. Partington, Geo. Bellasis Masfen, Samuel Crompton, Joseph Peel Caslow, Joseph Murphy, Alex. Wilson, David Bowman, Wm. Lees, Charles James Rix, Wm. Bates, Joshua Barlow, Henry Swift, A. W. Dumville, James Braid, Thomas Wood, Wm. James Wilson, John Aikenhead."

ROYAL COLLEGE OF SURGEONS:—PASS LIST. The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the college at the meeting of the Court of Examiners, on the 25th November:—Messrs. Philip Vincent, Camborne, Cornwall; Samuel Delprat, Hon. East India Company's Service, Bengal; William Mason, Ashby-de-la-Zouch; William Roberts, Manchester; Henry Wm. Freer Lomas, Derby; Henry Morris Simmonds, Linsfield, Sussex; John Thomson, Belfast; Alfred Stevens, Hammer-smith; John Joseph Coghlan, Old Cavendish Street; and Edward Dowson, Whitby, Yorkshire.

ORIGINAL COMMUNICATIONS.

CLINICAL ILLUSTRATIONS OF SOME DISEASES OF THE ŒSOPHAGUS.

By C. E. REEVES, B.A., M.D.

CANCER.

CANCER presents some distinctions from ulceration, in the point of the canal which it attacks. No part is exempt; but the lower half seems to present a greater tendency than the upper. Of the thirty-three cases which I have collected from various sources, the upper half of the canal, including the lower part of the pharynx, was affected in thirteen; in the remaining twenty, the lower half was the seat of the disease: in two only was the disease seated in the inferior fourth.

The fibrous and encephaloid forms of cancer seem to be of much less frequent occurrence than the cartilaginous; and Lebert (*Traité Pratique des Maladies Cancéreuses*, 444) makes the same remark on the general absence of fibrous element. He insists that it is rare to meet with general infection of the system with secondary deposits, the disease being generally confined to the œsophagus itself, or the parts adjacent. The same remark was made before by Rokitsansky (*Pathol. Anatomie*), who also observes that the œsophagus is very rarely the seat of secondary disease, and then only when the posterior mediastinum has been diseased. The case of Grisolle seems to have been of this character; and Desgranges (*Journal de Corvisart*, etc., an. x) mentions the case of a man, aged 50, who had on each breast a cancerous tumour of the size of an egg. He began to suffer from dysphagia, to which cough, expectoration, and difficulty of breathing, were soon joined. Some months before death, he brought up a little glandular body of the size of a pea, followed by some very offensive fluid; and he was enabled to swallow solids. Low fever, with night sweats, soon afterwards set in; and he died suddenly, eight months from the commencement of the dysphagia. In the lower part of the œsophagus, some scirrhous tubercles existed in a state of suppuration; the glands of the œsophagus were much enlarged. The right lung was loaded with tubercles in different stages; and the pleural cavity of that side contained fluid.

Males present a greater tendency to this disease than females, almost in the same ratio as in ulceration. In the cases, twenty-three were males, and nine females.

As regards age, men after the 40th year presented a greater tendency than females.

ENCEPHALOID DISEASE OF THE CANAL.

CASE I. ENCEPHALOID TUMOUR OF LOWER PART OF THE PHARYNX.† M., aged 45, six months before death, began to suffer from pain in the œsophagus, with dysphagia, first of solids, then gradually extending to fluids. The mucous membrane of the mouth and fauces was injected, and covered with white ashy coloured exudation. An obstruction to the introduction of an instrument from a hard body was met with in the lower part of the pharynx. Hectic set in, and at last the patient sank from inanition.

The lower part of the pharynx was the seat of a tumour;

it was red and livid grey in some points, in others white and creamy; it was ulcerated in parts, from which exuded a dark yellow foetid fluid. The tumour had so obstructed the upper part of the œsophagus, that a straw would pass with difficulty.

Dr. Hodgkin (*Lectures on the Morbid Anatomy of the Mucous and Serous Membranes*, lect. xviii) mentions an instance of encephaloid tumour of the lower part of the pharynx, and the first part of the œsophagus. Difficult deglutition existed. The tumour could be felt; it pressed the larynx forward. It was detached, and brought up.

Monro (*Morbid Anatomy of the Stomach and Gullet*) says that his father met with a case of fungoid disease of the pharynx and upper part of the œsophagus. The patient died from starvation. He himself met with an instance in the pharynx.

Baillie (*Morbid Anatomy*) speaks of a case which he saw, where the pharynx and the upper part of the œsophagus were diseased. Its surface was ulcerated. The case is no doubt the one which Monro's father saw.

CASE II. ULCER OF PHARYNX SURROUNDED BY SOFT WARTY GROWTHS: PERFORATION OF TRACHEA.* F., aged 36, had good health until fifteen months before death. She then began to experience difficulty and pain in swallowing. For nine months her symptoms gradually increased; her voice then became rather hoarse, and she had cough, but no expectoration: this was always excited by attempting to swallow. At this time, she had pain on the right side of the thyroid cartilage, increased by pressure, and attended by fulness of the parts. In a few weeks, she had considerable hæmorrhage, which occurred almost daily, and always followed pressure on the thyroid cartilage. The difficulty of swallowing, and the cough excited by doing so, at last became so distressing, that, for fourteen days before death, she was nourished by beef-tea injections.

An irregular cancerous ulcer existed in the pharynx; it had laid open the trachea immediately below the cricoid cartilage, and affected the right thyroid cartilage and arytenoid muscles. The mucous membrane around the ulcer was covered with soft warty growths.

CASE III. ENCEPHALOID DISEASE OF THE LOWER PART OF THE PHARYNX, AND FIRST PART OF THE ŒSOPHAGUS.† F., aged 45, single, in January 1827, began first to experience difficulty in swallowing dry food; and, by the 1st of April, it had greatly increased. When seen, on the 22nd of August, her pulse was 96, with symptoms of hectic. A gum elastic catheter was passed down five inches from the teeth, when it met with an obstruction. On being withdrawn, a little mucus tinged with fluid blood followed, and she was able to swallow a little fluid with great difficulty. Caustic was applied, and nourishing enemata were thrown up. She lost strength, and the dysphagia increased. The caustic produced so much irritation, that it was obliged to be discontinued. She was seized with dysentery, the discharge consisting of blood and sanies, but without pain or tenesmus. She died on the 12th of September.

The whole of the pharynx, from below the arytenoid cartilage, and for half an inch of the first part of the œsophagus, was covered with a yellowish white substance, with an uneven tuberculated surface, varying in consistence from lymph to soft cartilage. It varied in thickness from a quarter to half an inch, and contained many small cavities. The muscular tissue below it was of a pale yellow hue; and a gland situated behind the diseased part of the canal contained some viscid opaque fluid. The disease had so narrowed the canal, that a crow-quill could with difficulty be made to pass. The unaffected portion of the canal was unusually vascular. The heart and lungs were healthy.

CASE IV. SIMPLE STRICTURE; DILATATION, WITH FUNGOID DISEASE AND ULCERATION OF WALLS; TWO OPENINGS INTO TRACHEA; RINGS OF TRACHEA ERODED; ŒSOPHAGEAL GLANDS ENLARGED.‡ M., aged 50, nine months before death, came under Mr. Ward's care for stricture of the

* This person's sister died of the same disease at 27, and her mother at 56. They are not included in the table.

† Dr. Romberg, in Caspar's *Wochenschrift*, 1858.

† Mr. Cummin, *Edin. Med. Chir. Transact.*, vol. iii.

‡ Mr. Ward, in *Trans. of Path. Soc. of London*, vol. i.

œsophagus of twelve months' existence. For three weeks, he derived benefit from the use of bougies; but, the last time that one was used, blood was ejected and pain excited, which subsequently became constant, and led to the suspicion that cancer existed. The dysphagia gradually increased; and, ten days before death, violent dyspnoea came on, with inability to swallow, each attempt being followed by violent spasmodic cough, and the ejection of the fluid taken. His voice sank to a whisper.

In the œsophagus, immediately below the cricoid cartilage, was a narrow ring, so as just to admit the top of the little finger. Here the mucous membrane formed a valvular fold. Immediately below this was a dilation as low as the bifurcation of the trachea. The walls were thick and irregular with cancerous nodules; the mucous membrane was destroyed. Two openings existed, communicating with the trachea on its anterior walls. The fourth, fifth, sixth, seventh, and eighth rings of the trachea were eroded. The glands of the œsophagus were enlarged.

CASE V. ENCEPHALOID ULCERATION OF THE CENTRE; BRONCHIAL GLANDS ENLARGED.* F., aged 60, seen in July 1796, had been suffering six months from difficulty in swallowing. Food was arrested near the middle of the œsophagus; severe pain was excited, and it was returned. The same difficulty extended sometimes to fluids. She was much emaciated, and suffered considerably from low fever. Cough soon set in, with expectoration of purulent matter; and she sank in the following October.

The bronchial glands were hard and swollen; the lungs contained tubercles in considerable number. The œsophagus, for three inches of its extent in the centre, was in close contact with the lung; and here the walls were fungoid and ulcerated.

CASE VI. FUNGOID DISEASE OF UPPER PART OF CANAL; ENCEPHALOID TUMOUR IN THE CHEST; TUBERCLES IN THE LUNGS.† M., aged 64, of generally good health, had been a soldier from 1797 to 1814. For some time he had brought up filamentous mucus by regurgitation, early in the morning, while fasting. He had never suffered from any difficulty in deglutition till six weeks ago, when suddenly, while at a meal, difficulty was experienced. At the same time he commenced to suffer burning pain at two points, after the passage of both solids and liquids. The voice began to lose its tone. The appetite continued good, but severe constipation set in, and the respiration became oppressed. March 8, 1847, he entered the hospital. His face was of an earthy aspect; and there was considerable emaciation. His neck was prominent on the anterior and inferior part, most on the right. Sonorous râles were heard on both sides of the chest. Deglutition of liquids was yet possible; they descended very slowly, with a gurgling noise, at the points where the burning pain existed. On March 9th, an attempt was made to pass a catheter, but without success; and the same result followed the introduction of a bougie, on the 10th, by M. Baillarger. The moment it reached the bottom of the pharynx, severe pain and cough were induced, with expectoration of filamentous mucus. In the evening, the bougie was passed with greater ease and less pain; and it was repeated several times up to the 13th: then it was not introduced until the 16th, when a larger one was passed. In the evening of this day, spontaneous pain occurred at the spot where the pain was complained of in passing the instrument. On March 17th, the instrument passed. On the morning of the 18th, chills were experienced, followed by fever, which continued until death, on the 22nd. In the last days of life, the emaciation became extreme; the voice was nearly extinguished; the tongue brown; and there was an acid taste in the mouth.

At the *post mortem* examination, the œsophagus, an inch and a half down, presented a tumour which narrowed its diameter, covered by smooth, thin, delicate mucous membrane. This tumour projected from a larger one, situated at the entrance of the chest. It seemed to be formed of

tissue, which had all the characters of encephaloid matter: under the microscope. It was in a state of suppuration. Three inches lower down, a fungous ulcer, two inches and three quarters long, and nearly two inches broad: it was surrounded by two or three small tumours, consisting of encephaloid tissue. The vocal cords were thickened; and, near the commencement of the trachea, the same tumour projected. The recurrent nerves were embedded and untraceable. Tubercles existed in a healing state in the lungs.

CASE VII. SCIRRHOUS CONTRACTION OPPOSITE BIFURCATION OF TRACHEA; FUNGOID MASS BELOW.* M., aged 47, had generally good health, until after some mental trouble which affected him much, when he began to suffer from obstruction to the passage of food, which was at last rejected, mixed with mucus, but often thrown up without any difficulty. The dysphagia would suddenly return at meals; and it would be only with the greatest difficulty, and drinking copiously of water, that the morsel could be made to descend. He suffered from a constant sense of oppression in the centre of the sternum; and deglutition increased this symptom considerably. It was believed to be rheumatism, and was treated as such. The benefit which he derived from calomel and cicuta, and other antirheumatic medicines, strengthened this opinion. He died after vomiting blood for twenty-four hours.

The upper half of the canal was found dilated, and containing coagulated blood. Opposite the bifurcation of the trachea a scirrhus body existed, of the size of half-a-crown, and half an inch thick, which had materially narrowed the canal. From this point to within a short distance of the stomach, it was converted into a red fungoid mass, presenting scirrhus at parts; and here the canal had been narrowed to such an extent, that a small quill would with difficulty pass.

CASE VIII. FUNGOID TUMOUR IN THE LOWER HALF OF CANAL; LUNGS ADHERENT.† M., aged 70, entered St. George's Hospital on 22nd November, 1815. He was unable to swallow either liquids or solids, the difficulty existing opposite the cricoid cartilage. His health had been good until two months previously, when sudden and great difficulty in swallowing came on. During the next three weeks, on some days he was able to swallow fluids, and on others not; then he suddenly recovered the power of swallowing; but ten days before admission, the difficulty returned. He was quite free from pain until within the last few days, when weight and pain in the præcordia came on. He suffered more from hunger than from thirst. If he swallowed anything, it remained down for a few seconds, and was then returned. He expectorated a white, bitter, glairy phlegm. The œsophageal bougie was passed without obstruction; and, three weeks after his admission, he could swallow fluids without much difficulty; but his health continued to sink, and a short time before death, which took place on the 31st of January, an abscess formed under the armpit, and gave issue to a pint of pus.

The œsophagus, just where it entered the posterior mediastinum, was three times its natural size, and of a dark purple hue. On being opened, it was found to contain a large, soft, spongy, fungoid tumour. The lungs were both adherent; the rest of the viscera healthy.

The guard of a mail coach‡ had enjoyed good health until six months before his death, when dysphagia set in. He was placed under an alterative course of mercury; but he derived most benefit from the use of the armed bougie, which never failed to remove the obstruction in the canal. Even within the last month of life, he was enabled to swallow solids cut very small.

SCIRRHOID DEGENERATION OF THE CANAL.

CASE I. ULCER IN PHARYNX.§ M., aged 65, had, from an active, sober life, changed to a sedentary one, and at the

same time lived freely. An attack of vertigo was experienced; for this he was leeches. Soon afterwards, some slight uneasiness was experienced in the throat, which, in spite of treatment, went on increasing. When seen, his voice had become hoarse and low during three weeks; the submaxillary glands, particularly on the left side, were tumefied; and the motion of the lower jaw was extremely painful; and there was swelling and pain on the left side of the neck. The left tonsil was inflamed and ulcerated, and the back of the mouth participated in the disease. He had frequent cough, and a great excretion of mucus and saliva, amounting to from three to four pints a day. In swallowing, the greatest difficulty was with the first mouthful; if it passed, the remainder seemed to go well. A seton was introduced, and camphor and mercurial frictions were ordered, but to no purpose. At the end of a month, the deglutition had become more difficult; he could swallow only by depressing his head. The voice was more affected. His strength was much reduced. A sanious discharge was mixed with the mucus and saliva. Respiration was short and difficult; and death from suffocation ensued.

The maxillary glands, particularly the left, were much engorged; as was also the thyroid. The left half of the root of the palate was confounded with the pillars and the left tonsil, forming a scirrhus ulcer, which extended down the left side of the pharynx. A hardness also existed, extending from the tonsil down and back to the vertebra. The remainder of the pharynx and palate and uvula were swollen, hard, and inflamed. The epiglottis consisted of a mass of scirrhus disease, attached only by a point to the upper part of the larynx, which was also affected in the same manner; and at the base of the tongue, on the right side, an ulcerated excavation existed. The lungs were healthy; some fluid in the pleural cavities. The heart was small.

CASE II. ULCER IN UPPER PART OF CANAL; ENCEPHALOID TUBERCLES; THICKENING OF THE WALLS OF ŒSOPHAGUS AND TRACHEA.* F., aged 48, was delicate, and in the habit of spitting a large quantity of thick mucus. She became, after much mental anxiety, the subject of dysphagia, with difficulty in breathing, and sense of suffocation. At first these were slight; but, at the end of six months, they became very severe, and pain was experienced under the sternum on the left side, passing up to the shoulder and arm of the same side, and to the spine. The sensation of suffocation was very severe; under any mental emotion or exertion, it became very distressing, and also during the night; it was accompanied by cough, and expectoration of a thick white viscid matter. She gradually got worse; the right side of the neck became tumefied; her voice sank; and, in attempting to swallow, she was obliged to study her position. She at last died in an attack of suffocation.

The glands of the right side of the neck were greatly enlarged; some were of the size of pigeons' eggs, containing some dark offensive fluid. In the trachea, near its division, was a hard thickening of the size of a nut, which narrowed both the cavity of the trachea and that of the Œsophagus. In the last, from the pharynx to below the thyroid gland, an ulcer existed, surrounded by several soft white lardaceous tubercles. The stomach was small.

CASE III. TUMOUR IN UPPER PART OF CANAL; GLANDS ENLARGED; ABSCESS IN THYROID.† F., aged 35, the mother of several children, suffered from great difficulty in swallowing. The attempt to swallow a little milk produced severe pain in the ears, from the efforts necessary to make it descend. With the finger, a tumour could be felt deep in the pharynx. She was much troubled by viscid slime collecting. An attempt was made to introduce a small tube, but in vain. Leeches and blisters were applied.

May 10th (seven days after the use of these measures). She was much worse; she had pains shooting towards the ears, particularly the left. Calomel and sugar were rubbed on the side of the tongue.

May 29th. Her mouth was sore, but there was no im-

provement. A caustic issue was made near the thyroid cartilage; but, four hours afterwards, a severe attack of spasm came on, so as to threaten suffocation. Cold and an opiate gave some relief.

May 31st. There was pain in the epigastrium; and the breath was much affected.

June 7th. The voice and breathing were more natural; and she could swallow better. She had had frequent attacks of spasm.

June 23rd. She was better. She had to make many efforts before fluids could be made to pass from the pharynx into the Œsophagus.

July 12th. Bougies were passed for a week; and she was able to swallow better; yet the trachea seemed more affected. The issues were kept open.

July 16th. She was much worse; the breathing was very troublesome; the air seemed to pass through a constricted passage. She had frequent cough, which produced great faintness.

July 18th. The patient died.

A scirrhus tumour existed in the pharynx and upper part of the Œsophagus; and lower down in the canal were two small masses. The mucous membrane of the glottis and opening of the larynx was thick and dense; two small tumours existed in the larynx, which had so narrowed the canal, that only a small chink existed. The glands of the neck were swollen; and an abscess had formed in one of the lobes of the thyroid gland.

CASE IV. ULCER IN UPPER HALF OF CANAL.* M., aged 61, was seen on the 14th of May. He had indulged freely in spirits for eight years. He had been subject to cough in the winter; this had left him six weeks before he was seen, and was succeeded by difficulty in swallowing solids unless well moistened, and then only in very small quantities at a time. The difficulty had greatly increased, and was attended with constant pain in the throat, shooting up to the ears and jaws, with uneasiness in the lower part of the Œsophagus. The morsel seemed to meet with an obstruction immediately behind the cricoid cartilage; it was arrested there for a short time, and then seemed to pass; but at times it was rejected, mixed with phlegm. The voice continued good. He was somewhat emaciated. A bougie was arrested seven and a half inches from the teeth, producing much irritation, and was followed by the ejection of mucus streaked with blood. Two other attempts were made to pass it, but both failed. On the 19th of May it succeeded, and gave the sensation as if passing through a piece of paper.

May 20th. He was able to swallow better; yet the pain in the ears and præcordia were very severe.

May 28th. He was better. The bougie passed with more ease, but gave more pain, and was followed by the rejection of mucus streaked with blood. The pain in the præcordia was severe.

July 14th. A larger bougie was passed; but, on the 16th, it would not pass, and the pain in the lower part of the Œsophagus was more severe. An attempt was made on the 21st, but it failed; severe coughing and retching being excited. Recourse was then had to the caustic bougie: its use was followed by severe burning pain.

August 29th. The caustic bougie had been frequently used during the month; but the dysphagia had much increased, and the emaciation had made great progress, as also had the pain, and at times blood had been spat up. The disease gained ground; and, on the 22nd of October, puriform fluid was brought up, which increased in quantity, and was mixed with the mucus. On the 25th, all attempts to swallow produced violent convulsive efforts in the stomach and diaphragm: nothing would descend. Death took place on the 5th of November.

The Œsophagus, behind the cricoid cartilage, was nearly obliterated by thickening of its coats. It was ulcerated for the space of an inch above and below the constriction; the ulcers had raised jagged edges, and their surface was covered

* Desgranges, Journal de Corvisart, Leroux, et Boyer. An. ix.
† Sir Charles Bell's Surgical Observations.

* Mr. Jeffrey's Cases in Surgery.

with a soft flocculent kind of slough. The lower part of the canal was more vascular than usual.

CASE V. SCIRRHIOUS DISEASE OF THE CENTRE OF THE CANAL.* M., aged 40, three months previously, began to suffer from pain and uneasiness between the shoulders; this was followed, in the course of a few weeks, by obstruction to the passage of food near the upper part of the sternum, and by great inconvenience from a copious secretion of glairy ropy mucus. Of late, the pain between the shoulders was so severe as to be likened to a red hot poker boring through the spine; at times, shooting along the ribs. It was with great difficulty that a little bread and milk could be got down by pressing the throat with his finger and thumb. A bougie met with an obstruction, eight and a half inches down; great irritation followed its use; but, in a few days, his deglutition became much easier. He soon, however, relapsed, and even milk was with difficulty made to descend. He died.

No *post mortem* examination could be obtained.

CASE VI. SCIRRHIOUS DISEASE OF THE LOWER PART OF THE ŒSOPHAGUS.† M., aged 60, had suffered from difficulty in swallowing for six months. Any attempt to swallow a little water excited a kind of regurgitating effort in the lower part of the pharynx, with cough, a little only seeming to pass; before reaching the stomach, it again met with an obstruction, where it was detained for a few minutes, and then rejected. The obstruction at the lower extremity had been only observed during the last few days.

After death, the lower part of the Œsophagus was found scirrroid. There was no thickening in the upper part of the canal, but, two inches down, indications of inflammation existed, extending to within four inches of the cardiac orifice of the stomach.

SCIRRHIOUS DEGENERATION AFFECTING THE TRACHEA, VERTEBRA, AORTA, AND PLEURAL CAVITIES.

CASE I. SCIRRHIOUS DISEASE OF THE ŒSOPHAGUS, OPPOSITE THE FOURTH DORSAL VERTEBRA; TWO OPENINGS COMMUNICATING WITH THE TRACHEA.‡ M., aged 70, tall and large made, had not enjoyed good health for the last ten years, and for some months past had lost flesh. Three months ago, he experienced, while at dinner, difficulty in swallowing, which had since increased to such an extent, that soft or liquid food only would pass.

When seen on July 10th, 1838, he had no pain, but at times a burning sensation near the centre of the sternum. A probang, a quarter of an inch in diameter, was passed. On the 22nd, he was quite unable to swallow for thirty-six hours; at last, a small tube was passed, and through this food was introduced. In the evening, the power of swallowing returned. A probang was repeatedly passed. On October 17th, it was observed to be covered with slimy fœtid matter, and for several days fever existed, which then declined, and he was enabled to swallow better than he had done for a considerable length of time. In the last week of December, cough came on, accompanied with dyspnoea: food increased the cough much: and severe burning behind the sternum was at the same time excited. The skin was hot and dry; the pulse 108; the tongue coated and dry; and the emaciation great. Even liquids were sometimes rejected. The debility became, on the 9th of January, so great, that he was obliged to keep his bed. Fluids were returned by the cough. The pulse was 110, small; thirst was severe; the bowels acted twice daily. The pulse increased up to the evening of death, the 12th, when it was 120.

The Œsophagus was dilated in its upper part; but opposite the fourth dorsal vertebra, to which it adhered closely, its walls were thickened, and its calibre diminished to one-eighth of an inch by a rough tuberculated substance, for two inches in length, covered by sanious matter. Openings existed, communicating with the trachea.

CASE II. SCIRRHIOUS DISEASE BELOW THE CENTRE, THREE OR FOUR INCHES IN EXTENT, AFFECTING THE SPINE: COM-

MUNICATION WITH THE TRACHEA.* M., aged 56, had been in the habit of drinking freely of spirits. A week before Christmas 1844, he began to experience some difficulty in swallowing, particularly solids. This state continued a month, when, after drinking a large quantity of rum, the difficulty increased, and was accompanied with pain in the epigastrium. He then applied to the hospital, and at the end of a week, by the use of bougies, he was much relieved. A relapse soon took place, and for two months he sought no treatment. When seen, the emaciation was extreme; and he suffered from a constant sense of burning constriction in the Œsophagus, with cough and expectoration of thick mucus, tinged with blood; the thirst was intense; he had headache; and his bowels were severely confined. The pulse was 90; the skin cool; and urine scanty. Swallowing excited severe pain in the centre of the sternum, and, in a few seconds, the morsel was returned by an inverted action; and the little which reached the stomach was often rejected by vomiting, mixed with highly offensive fluid. An elastic tube was arrested near the centre of the sternum. During the last few weeks of life, he was sustained by nutritive enemata. He at last sank from inanition.

The Œsophagus, near its centre, adhered firmly to the spine. For three or four inches of its length, down near where it passed through the diaphragm, it was in a state of scirrroid ulceration. An opening existed, communicating with the trachea. The bronchial tubes were filled with frothy mucus, and the bronchial glands were enlarged and mottled. The bodies of the vertebræ and the intervertebral substance, where the disease was in contact, had begun to be involved.

Aussant (*Diss. sur les Squirrhes de l'Estomac*, cited by Dr. Walshe) mentions a case where death occurred from the spinal cord becoming implicated; the intervening vertebræ were much softened. I have not been able to obtain this work, but a copy of it exists in the library of the Ecole de Médecine.

CASE III. SCIRRHIOUS DISEASE OF THE ŒSOPHAGUS, OPPOSITE THE BIFURCATION OF THE TRACHEA: ABSCESS BETWEEN THE TWO CANALS, COMMUNICATING WITH BOTH: THE LEFT RECURRENT NERVE IN PART DESTROYED.† M., aged 41, a bricklayer, of intemperate habits, had suffered from difficult deglutition during two years. Nine months ago, his voice became altered in sound. Food met with an obstruction in the upper part of the sternum, large quantities of fluid being necessary to assist its descent. Regurgitation often took place, with violent retching and coughing. On the 18th of January, he entered the London Hospital. On the 19th, a small probang was introduced; it met with an obstruction at the lower part of the pharynx; and lower down, a second obstruction was met with, after surmounting which the instrument entered the stomach. Pain was excited, which lasted some hours. He could now swallow food cut up very fine, with thin fluids. The probang was passed several times, but each time the difficulty in doing so was increased. In February, the difficulty in deglutition had increased much; milk and thin puddings were got down with great difficulty, and in very small quantities. The voice was reduced to a loud whisper. His health soon began to suffer; his face became of a bluish tint; the breath was highly offensive; and, by the 14th, nothing but liquids would pass. Soon after this, if fluids were taken, they seemed to remain some seconds, and were then rejected by coughing. Thick mucus collected in the throat, and for three days nothing would pass. A small tube was passed down to the lower stricture, and nutritious fluids injected three times daily. On January 22nd, the skin became hot and dry; the pulse 118; the cough was very troublesome; and the lower stricture was more contracted. On January 23rd, he was much worse; pulse 136. A fit of coughing came on while talking; a quantity of dark fœtid matter was brought up; and he fell back and expired.

The thyroid gland was condensed, and consisted of a

* Howship, Practical Observations on Indigestion.

† Ibid.

‡ Dr. Wyman, American Journal of Medical Science, 1839,

* Mr. Harris, Edin. Med. and Surgical Journal, vol. lxi.

† Mr. Barratt, in Lancet, 1847.

number of nodulations, passing back on the left side, separating the œsophagus from the trachea, and involving the carotid vessels. On section, a dark creamy substance exuded from some, while others gave issue to foetid matter. Between the œsophagus and the trachea, an abscess existed, containing foetid matter, and communicated with both the canals. The œsophagus, opposite the bifurcation of the trachea, was so narrowed as scarcely to admit a goose-quill. The constriction was formed of tissue, which under the microscope showed cancer-cells. The carotid vessels and jugular veins were implicated. The recurrent nerve of the left side ended in a nodule, in the wall of the abscess.

CASE IV. SCIRRHOUS ULCER: OPENING INTO TRACHEA AND AORTA.* M., aged 42, began, in the course of the summer of 1840, to suffer from difficulty in swallowing. He entered the Hospital of Zurich in June 1841. The deglutition of solids had been nearly impossible for some weeks, food being arrested opposite the ensiform cartilage. Liquids would pass only, and in small quantities. At the point where the obstruction existed, severe burning pain was experienced. A probang was passed, but it would not enter the stomach; and severe pain was excited. An attempt was again made, and on the next day he vomited up three pints of frothy blood, and died in an hour.

A carcinomatous ulcer existed opposite the bifurcation of the trachea, of the size of a five-shilling piece; it communicated with the last by an opening of considerable size, and with the aorta by another.

CASE V. ULCER OF LOWER PART OF THE CANAL: PERFORATION OF THE RIGHT PLEURAL CAVITY.† M., aged 60, was of good health, but much affected from losses and anxiety. His digestion first suffered; but, in April 1841, dysphagia first set in, the point of obstruction being near the epigastric region; and by June it had made so much progress, that great difficulty was experienced even to the passage of fluids. A bougie was attempted to be passed, but without success. Several other efforts were made with smaller ones, and at last the obstacle was surmounted; and, by means of a narrow elastic tube, nourishment was for a month conveyed to the stomach. One morning, more resistance than usual was met with, and a large quantity of putrid sanious matter, with a portion of disorganised fleshy substance, which crepitated when cut, was ejected. From this time, the deglutition became easier; and, in a few days, he was able to swallow an egg and soup without difficulty. On August 15th, when swallowing some soup, he was taken with severe cough, attended with purulent expectoration. Any attempt to swallow fluids was followed by great danger of suffocation. Thirst was intense. A tube was introduced, for the purpose of passing fluid into the stomach; but, from the cough and suffocation which it produced, it had evidently entered the chest. A few days after, another attempt was made, and half a glass of drink injected. He immediately fell back: it had all passed into the chest, and it was only with the greatest difficulty that it was got rid of. Enemata alone were used. He died twenty days after, and six months from the first appearance of the disease.

The œsophagus was destroyed for two inches. About an inch and a half above the diaphragm, the ulcer had ragged edges, and was of a livid colour. A perforation existed at this point, which had penetrated the posterior wall of the mediastinum into the right side of the chest.

CASE VI. SCIRRHOUS CONTRACTION; ULCER OF THE LOWER PART OF THE CANAL; PERFORATION OF THE RIGHT PLEURAL CAVITY.‡ A female entered the hospital for surgery, three weeks before death, with all the appearances of cancer, suffering from an almost complete obstruction to the passage of food. She suffered from constant acute pain in the situation of the ninth dorsal vertebra, and here the obstruction existed to the passage of food, which was the moment it reached this point, rejected, with violent, painful,

spasmodic retching. She had constant fever; the respiration was natural. The disease had commenced two years previously: at first it was slight, then had gone on gradually increasing. Opium in large doses alone gave her relief. A bougie was introduced, and a firm obstruction was felt; severe pain followed its use, and recurred whenever the instrument was used. She refused to allow enemata to be administered, and at last sank. The œsophagus opposite the tenth dorsal vertebra was converted into a scirrhus cartilaginous substance; two inches below this point a ragged ulcer existed; at one point all the coats were destroyed, and the wall of the posterior mediastinum was opened into the right pleural cavity. The lung had a small ulcerated point, which had not penetrated the parenchyma, surrounded by lymph. No fluid existed in the cavity. The stomach was much contracted.

SCIRRHOUS DEGENERATION WITH DISEASE OF THE LUNGS.

CASE I. ULCER IN UPPER PART OF THE CANAL; TUBERCLES OF THE LUNGS.* M., aged 68, had good health up to April 1842, eight months before death, when he began to suffer from difficulty in swallowing, which at last increased to such an extent, that first solids, and then liquids, refused to pass. His aspect altered much, and became of a pale straw hue; he emaciated rapidly, and at last died from inanition. A. Berard attempted in vain to pass a tube, for the purpose of introducing food into the stomach. In the œsophagus, a short distance below the hyoid bone, the canal was narrowed so as scarcely to admit a small catheter, by a scirrhus contraction, which enveloped the whole circumference of the canal, and was nearly an inch and a half in length. Its surface was unequal, in some places of a dark grey, and in others of a dirty yellow colour; in its upper part several excavations existed. In the small intestines, near the cæcum, a thickening of all the membranes existed, for about an inch and one-sixth in length; the part was hard, and crepitant when cut, but under the microscope gave no indications of cancerous structure. Some tubercular granulations were also observed in the submucous cellular tissue. The lungs contained tubercles in the crude state. The surface of the cancerous mass, under the microscope, consisted of a mixture of mucous, epithelium, blood-globules, and cancer-cells. The tissue itself consisted of fusiform cells, with but little of the fibrous element.

CASE II. ULCERATION IN LOWER HALF OF CANAL; NARROWING BELOW COMMUNICATION WITH RIGHT LUNG.† M., aged 53, of bilious sanguine temperament, began to suffer, when 40 years old, from disordered digestion from no known cause. Pain was experienced in the epigastrium after eating, with acid eructations; and the food was often returned to the mouth some time after being taken. The mouth was often filled with saliva, like that which occurs before vomiting. Vomiting at last came on; and he was scarcely able to take anything which was not rejected. At the age of 44, he became unable to work, from severe pain in the epigastrium, which extended to the sides and shoulders; and in this state he continued for four years, the vomiting being very severe. He then became better for some months, and was at last able to return to work, but only for fifteen days, when the symptoms returned with redoubled violence, and he was soon reduced to a state of extreme emaciation. Various measures were had recourse to, but in vain. By strict confinement to a milk diet for two years he found himself much better, and he gained strength and the vomiting left him. At the age of 53, in carrying something heavy, he heard something crack in his chest, which was followed by severe pain shooting up to the shoulder. Six months after this, he entered La Charité, considerably emaciated; his face was not altered: the appetite was good, but deglutition of solids was very difficult. The first morsel descended with ease to the middle of the chest, where it became arrested; but the second was arrested at the lower part of the neck. Violent cough came on, and they were returned.

‡ Mr. Wardrop, in *Lancet*, 1837.

* Lebert, *Physiol. et Pathologie*, tom. ii.

† Martin, *Bibliothèque Médicale*, tom. xxiv.

Drinks, even when swallowed slowly and in small quantities, produced cough, and were rejected in the form of froth; and during the cough he was in great danger of suffocation. There was no fever; but in the evening he had chills. In a few days, however, fever manifested itself, and he gradually sank. The œsophagus opposite the sixth dorsal vertebra was in a state of cancerous ulceration: a short distance below this point it was impossible to pass a pin. The right lung adhered closely to the ulcerated part of the canal; and here an opening existed, which communicated with a cavity holding six ounces of fluid, grey and fetid; its walls were grey and formed of the substance of the lung. The bronchi and trachea contained the same kind of fluid as in the abscess. The stomach was much contracted, and the mucous membrane was of a very deep colour.

CASE III. SCIRRHUS OF THE WALLS OF THE ŒSOPHAGUS; ABSCESS IN THE RIGHT LUNG.* F., aged 44, when seen, 15th Nov., 1832, had been ill six months. Food was returned unaltered, mixed with mucus; and at times, but very rarely, a fluid like coffee-grounds was brought up. She had intense thirst; respiration was free, and the pulse regular; the bowels were very costive. She died on 14th Jan. 1833.

The œsophagus was narrowed from cancerous thickening. Immediately above, an opening existed which communicated with a cavity in the substance of the right lung, which contained an ounce and a half of brown fluid. The walls were irregular with a gangrenous appearance, and the substance of the lung for two inches in extent around it was hard and dense. The œsophagus adhered closely to the right lung.

CASE IV. SCIRRHOUS NARROWING, WITH ULCERATION OF LOWER HALF OF CANAL; CAVITY IN RIGHT LUNG; STOMACH INFLAMED.† M., aged 46, a retired captain of the navy, after experiencing much mental anxiety in 1831, began to suffer from dull pain in the course of the œsophagus, and difficulty in swallowing solids. At first, great part of the canal seemed affected; but later, the disease appeared confined to several points, so that the food was arrested two or three times in its descent, and at the end of a month it seemed to confine itself to the lower part. Here the morsel was arrested, and he was in great danger of being suffocated, to avoid which he drank large quantities of water. At last he was obliged to confine himself to broths. The pain was situated behind the sternum, and was much increased by talking, or coughing, or any mental emotion. Leeches were applied, first to the seat of pain, then to the anus, and strict rest enjoined; but this he neglected, got about much, and spoke frequently in public. He became much worse, the pain radiated towards the vertebral column, and extended to the right side of the chest. This last had a neuralgic character, and followed the course of the intercostal nerves, sometimes passing up along the spine. Under the idea that it might depend on some syphilitic affection, he had recourse to some nostrum. Its use was followed by the discharge of glairy mucus, often insipid, but at times acid. The quantity regurgitated became at last considerable, and the difficulty to the descent of food was so great that only a tea-spoonful of fluid at a time, and latterly often not even this, would pass. The pain at this time became lancinating, and the mucus was at times streaked with blood. Fever also lighted up, but its accessions were irregular. The efforts to get rid of the mucus at last became so painful, that the pharynx was constantly convulsed: it was of a deep red colour, and the tongue became of the same hue. A constant sensation existed in the stomach as if a ball was there, which threatened to suffocate him. Every attempt to swallow excited convulsive motions in the throat and œsophagus, which were propagated to the muscles of the abdomen, and caused them to act as in vomiting. On the 8th of September he began to expectorate phlegm; and auscultation discovered, in the posterior part of the right side of the chest, indications of pneumonia. The face was swollen, and the skin hot; and diarrhoea set in. Respira-

tion became more and more difficult, particularly when he was drinking. On the 10th, the expectoration was highly fetid, grey, and thin. He died on the 11th, retaining his mental faculties to the last.

The right lung was soft, the slightest pressure reducing it to a greenish, black, fetid fluid: this change was most perceptible near the insertion of the bronchial tubes and vessels. A large cavity existed in this lung, which communicated with the œsophagus, with which it adhered most intimately. The œsophagus, in its lower half, was greatly narrowed, and presented a great number of ulcerations, surrounded by pale friable vegetations. Most of these ulcerations were the commencement of small sinuses, nearly all of which ended in a pouch in the posterior wall, formed at the expense of the muscular tissue. This cavity communicated with the one in the lung. The whole of the diseased portion of the œsophagus was softened; and on its being pressed or cut, cerebriform matter exuded. The nerves of the canal showed no change. The stomach presented some red patches; and the duodenum was also injected for a short distance in its upper part. The capsule of the spleen was in some parts cartilaginous, in others ossified.

Chassaignac, in his report on this case, mentions an instance of a similar nature, which fell under his notice at the Hôtel Dieu de Nantes. The œsophagus and the right lung were affected in the same manner.

CASE V. SCIRRHUS OF LOWER PART OF CANAL; ABSCESS IN LEFT LUNG; MIDDLE MEMBRANE OF STOMACH WHITE AND CARTILAGINOUS.* M., aged 50, a surgeon, had indulged freely in drink. In September 1751, he began to experience a pain just above the orifice of the stomach, on taking either solids or fluids; the pain was propagated up the canal, and at last the affection increased to such an extent, that food was rejected. When seen in January 1752, he attempted to swallow some milk, which was returned; and the same occurred with a little water; the rejected matters were mixed with viscid mucus, and the same kind of mucus was brought up in the morning. The pain was referred to a point a little above the ensiform cartilage. On swallowing, it was likened to a sense of constriction, but most frequently that of a worm like motion. He had a great desire for cold drinks. At times, the difficulty in swallowing became so great, that he was obliged to abstain for two or three days: he would then suddenly experience a sensation as if the passage to the stomach was free, and some thin pulpy food would pass; but the obstruction would soon return, and all he took would be rejected. He grew worse; the pain became more severe, hectic set in, and the introduction of drinks into the stomach became impossible. Death ensued on the 18th April.

In the left lung, close to the œsophagus, was a large cavity, containing yellow pus. A scirrhus tumour, of the size of two fingers, existed near the orifice of the stomach; the canal was narrowed for a short distance, but above this it was much dilated. The stomach was empty, and its middle membrane was white and cartilaginous. He had coughed slightly during the last few days of life, but he had complained much of a suffocative sensation.

CASE VI. SCIRRHOID TUMOUR OF LOWER PART OF CANAL; RIGHT LUNG DISEASED; COLLECTION OF SEROPURULENT FLUID.† M., aged 40, had been delicate in childhood; but as he approached manhood had gained flesh and strength. He began to suffer from dysphagia, accompanied by a dull pain at the top of the epigastrium. Six years passed, and dysphagia gradually established itself: he died after a year's extreme suffering. Five or six weeks before death, cough set in: he died from suffocation in a fit of coughing.

The lower extremity of the œsophagus, and the cardiac orifice of the stomach, were both hard and thick, and formed a scirrhus tumour an inch and a half long, like a ring pierced by an opening three or four lines in diameter. The mucous membrane was destroyed. The stomach was healthy.

† Desgranges, Journ. de Med. Chir. et Pharmacie. An. ix.

The right lung was adherent; its substance was soft, and corroded in great part: its base was ulcerated, and even putrified: posterior to it was a seropurulent collection, two quarts in amount existed.

CASE VII. SCIRRHUS DISEASE THREE INCHES IN LENGTH, BELOW THE CENTRE OF THE ŒSOPHAGUS; THE VERTEBRÆ ENLARGED; MUCOUS MEMBRANE OF STOMACH INFLAMED; PLEURITIS; FLUID IN RIGHT PLEURAL CAVITY.* M., aged 64, had good health until five months back, when from exposure to cold, he began to suffer from cough, but without expectoration. At the end of a month, pain was experienced in the ensiform cartilage, coming on after eating, and attended with difficulty in swallowing. Both these symptoms had become much worse at the end of five weeks. When seen, on September 23rd, emaciation and debility had been severe for the previous two months, and he had not been able to take either solids or fluids; the last passed down without difficulty, but, after two minutes, they were gulped up without difficulty. He had severe cough, with copious expectoration of mucus. The bowels were very confined; the appetite good; the pulse 54; the skin cool and dry; the tongue clean and moist: he slept well.

Sept. 26th. He was able to keep down a little broth. His urine was high coloured.

Sept. 27th. The cough was troublesome, with abundant expectoration.

Sept. 29th. He was able to keep down a little milk. He suffered much from pain in the epigastrium, accompanied with tenderness. Pulse 70. His cough was severe; there was no r le in any part of the chest.

Sept. 30th. He had severe pain since the previous day under the false ribs, after injecting some tea and whey. In the night, the opening of the Œsophagus became free, and he swallowed and retained a large bowlful of milk and stirabout.

For the next twenty-four days, there was little change in his symptoms: one day he retained the food taken, at others not. He was seized in the night with severe pain under the right false ribs, and much tenderness existed at this point: he could not draw a full breath. The cough was severe; the thirst great; pulse 56. The next night, the pain was so severe as to excite a kind of convulsion. He died three days after the pain in the false ribs set in. During this time, he took nothing.

The Œsophagus, two inches above the cardia, was for three inches of its length in a state of scirrhus, in some parts an inch and a half thick, and would only admit of the introduction of a goose-quill. The mucous membrane, above this point, was thickened and soft; below, it was inflamed. The mucous membrane of the stomach was very soft, and its coats were transparent. The spleen was soft. The vertebra and the inter-vertebral substance opposite the diseased part of the canal were enlarged, but not diseased. In the right pleura a pint of fluid existed, which contained shreds of recent lymph, the lower part of the inferior lobe of the lung covered with lymph.

The vomiting after the fluid had entered the stomach, must have been caused by the inflamed state of that organ.

SCIRRHUS DEGENERATION, WITH AFFECTION OF THE LUNGS, ETC.; CANCER, PRIMARY OR SECONDARY, IN OTHER ORGANS.

CASE I. ULCER OF LOWER PART; PERFORATION; CAVITY IN RIGHT LUNG; CANCER OF STOMACH; ENLARGED ŒSOPHAGEAL GLANDS.† F., aged 38, the mother of six children, complained of severe pain in the stomach, which was much increased by food. In the month of June of the same year, a difficulty in swallowing solid food was experienced, and it was often rejected mixed with a large quantity of mucus. By the use of resolvents, she became so much better, that she believed herself cured; but it returned, and made very rapid progress. In this state she was seen by Van Doeveren. All food was immediately rejected by regurgitation, mixed with mucus, and accompanied by severe pain. She seemed to derive some benefit, and gained strength, from

milk diet, cicuta, sulphuret of antimony, and calomel, carried to salivation. But in March of the next year she became worse, and the symptoms made rapid progress. The stomach was much distended with wind, and she had painful acid eructations, as well as fever, with small pulse, and extreme debility. She also experienced in the Œsophagus an obstruction to the passage of food, as if from a collection of mucus. Milk or any other fluid was immediately rejected, and with it a grey substance like corrupted milk, with an acrid odour; and the same odour existed in the mucus. Solids were arrested at this point, exciting the most excruciating pain and anxiety, with faintings. She refused to allow nourishing enemata to be injected, and sank on the 14th of April, 1777, rejecting to the last matter like corrupted milk.

Between the right carotid artery and the trachea was an enlarged gland, nearly cartilaginous in structure, and of the size of a pigeon's egg. The Œsophagus, opposite the ninth dorsal vertebra, was hard and thickened. The right lung adhered to the pleura; and, on attempting to separate it, a cavity was ruptured, from which ran out ashy coloured grumous matter, like putrid milk. A free communication existed between this cavity and the Œsophagus, the borders of which were unequal and gangrenous. Below this point, the canal for two inches was so narrow, that a pen with difficulty would pass. The walls of the stomach were thin; and on the lesser curvature a rather large scirrhus tumour existed, midway between the cardia and pylorus.

CASE II. SCIRRHUS THICKENING OF THE LOWER PART OF CANAL; ALTERATIONS OF THE WALLS; SCIRRHOSIS OF STOMACH AND DUODENUM, PANCREAS, GLISSON'S CAPSULE, AND DUCTUS COMMUNIS CHOLEDOCHUS.* F., aged 26, married, of delicate health, while at dinner was suddenly taken with severe pain in the epigastrium; this confined her to her room for some days, and then left her, but returned at different times. She was seen by Mr. Gaitskell, three months before her death, then suffering from constant aching pain behind the lower part of the sternum, descending to the epigastrium and back to the spine, accompanied by nausea and retching. The pain varied in intensity, but was always better when the stomach was distended with food, the entrance of which was always attended with great difficulty. A bougie was introduced, and a hardness was felt. On its withdrawal, pain was experienced. It was not again passed for a month; then, for the first week, relief was experienced, but afterwards it aggravated the symptoms. Mr. Cline advised the swallowing of a weak solution of sulphate of zinc; but, at the end of three weeks, she became unable to swallow without severe pain and retching. She refused all food; and, after languishing for a fortnight, died, suffering from unquenchable thirst. Both her mother and her sister had died of the same disease—the first at fifty-six; the other at twenty-seven.

The Œsophagus, from the pharynx down to within one inch of the cardia, was white and firm, like ligament. At this point it was scirrhus; and this state extended along the lesser curve of the stomach to below the pylorus. The head of the pancreas, Glisson's capsule, and the ductus communis choledochus participated.

CASE III. SCIRRHUS DISEASE OF ŒSOPHAGUS TWO INCHES FROM DIAPHRAGM; SCIRRHUS OF POSTERIOR PART OF STOMACH, ADHERING TO DIAPHRAGM; ABSCESS IN LOWER LOBE OF LEFT LUNG, COMMUNICATING WITH STOMACH.† M., aged 34, had suffered at times for a year from pain under the ensiform cartilage; some irregularity in diet destroyed his appetite and digestion, and he lost flesh. When seen in November, he was much reduced, with great difficulty in swallowing solids, which, near the orifice of the stomach, produced much pain. Sometimes they passed without difficulty, but were soon thrown up mixed with phlegm. Liquids descended, if swallowed slowly, without difficulty. He had a sense of constriction across the epigastrium, but no tumour or tenderness on pressure; the pulse was good; the bowels were

* Dr. Graves, in Dublin Med. Journal, 1830.
† Bienland de Sana et Morb. Œsophagi. Obs. I.

* Mr. Gaitskell, London Medical Repository, 1812.
† Dr. Taylor, Edin. Medical Essays, vol. II.

constipated. In December, he suffered from symptoms of stone in the kidney for five days. In March, night sweats came on, and he brought up two polypus-like substances, followed by a sharp pain in the breast, which continued for four days. At the end of fourteen days, another polypous substance was brought up; but no pain followed, and the night sweats subsided. In May, he had a slight return of the affection of the kidneys; and, at the same time, he became sensible of a hardness in the left hypochondrium. Soon after this, diarrhoea set in; the stools were whitish; he lost flesh and strength rapidly; and died in the middle of June.

The omentum was everywhere scirrhus, and contained many little abscesses. The liver, spleen, and stomach, were covered with small white tumours. The stomach adhered to the diaphragm by its posterior part, by a scirrhus mass. The intestines seemed a little inflamed, and adhered to each other. The kidney contained a stone. Some fluid was found in the left pleura. The lower lobe of the left lung adhered to the diaphragm; it contained an abscess, containing pus, with some viscid brown fluid. An opening passed from this abscess through the diaphragm into the stomach. The œsophagus, two inches above the diaphragm, was in a state of degeneration like cartilage. The glands at the divisions of the trachea contained calcareous spongy matter, enclosed in a thick membrane.

CASE IV. SCIRRHOUS DISEASE OF ŒSOPHAGUS, THREE INCHES FROM CARDIA: TUBERCLES IN THE LUNGS: LIVER AND PANCREAS CANCEROUS.* M., aged 51, two years before, had had an attack of spasm in the stomach, followed by jaundice, which soon yielded to treatment. In February 1847, his health began to fail, appetite became bad, and he suffered from dyspepsia. At the same time, he experienced severe pain in the centre of the last bone of the sternum, with difficulty in swallowing. When seen on April 5th, there was no pain; the face was sallow and leaden; the tongue clean; pulse weak; dry cough; and much emaciation and constipation. Purgatives and quinine were given. On February 14th, he suffered much from heartburn, pyrosis, and sickness. The difficulty in swallowing was much increased: fluids only could be swallowed. He continued his work, that of a turner, up to the latter part of the month. He died on the 5th of May.

In the apex of the right lung, soft tubercles existed; in the left, the same, with also two small cavities. The œsophagus, three inches from its lower part, was nearly obliterated from cancerous degeneration of its walls. Above this point, the canal was much dilated. The liver contained two tumours, of a cancerous character; and, in the head of the pancreas, two tumours also existed.

CASE V. SCIRRHOUS DEGENERATION OF A GREAT PART OF THE ŒSOPHAGUS: CAVITIES IN THE RIGHT LUNG: CANCER OF THE STOMACH, LIVER, AND PANCREAS.† M., aged 55, had suffered from one and a half to two years, from disorder of the stomach, with difficult digestion. He had got much worse during the last four months; and to which had been added, for some weeks past, pain both in the stomach and in the œsophagus, accompanied with difficulty in swallowing. When seen on the eighth of August, his face was of an earthy hue: emaciation was not extreme. There was deep seated pain in the stomach, not increased by pressure; and also in the œsophagus, particularly in swallowing; the morsel being often arrested and rejected, mixed with acrid mucus. The dysphagia became so severe, that he was restricted wholly to milk. No thirst. Bowels natural. The voice soon became changed in tone, and cough also came on; and there were some harsh sounds in one of the lobes of the lung. Pulse 90, feeble. Under the use of iodine, externally and internally, he improved for a fortnight; but then, from no appreciable cause, the breathing became difficult, and the pain and difficulty in swallowing as before. The quantity of mucus brought up greatly increased, and continued to do so until

death, and was at last mixed with purulent fluid. The difficulty in swallowing increased to such an extent, that even fluids would not pass without great difficulty and severe pain. The pain in the stomach and œsophagus increased in severity. The cough was severe, accompanied with purulent expectoration. The pain in the chest was severe, and mucous râles were heard. The fluid brought up soon had a highly fœtid odour, and he at last sank on the 3rd of October.

Fluid existed in the pleural cavities, and the pericardium contained three ounces of reddish serum. In the right lung, a large cavity existed, containing highly fœtid yellow ichorous matter, and portions of broken down lung. A smaller one, the size of a walnut, existed near the trachea; and in the apex, was a mass of tubercles, of the size of a hazel nut. The œsophagus was as thick as the arm, from fibrous scirrhus degeneration, nearly throughout. In some parts, the walls were four or five lines thick, and irregular. Nearly the whole of the canal was ulcerated, and covered with slimy and ichorous fluid. The muscular coat was affected here and there. Deep excavations existed, and the adjoining tissues were affected. The stomach was empty, and rather shrunken. On the left side of the cardia, a scirrhus mass, of the size of a hen's egg, existed, in close connexion with some degenerated lymphatic glands; and, under its serous coat, small cancerous masses were found, varying in size from a linseed to a bean. They appeared to consist of degenerated lymphatic glands. The liver was large, and contained a great number of whitish yellow cancerous masses, varying in size from a linseed to a pigeon's egg. The head of the pancreas had begun to participate in the mischief.

CASE VI. ULCER IN UPPER PART: ANEURISM OF AORTA: BLOOD IN LEFT PLEURAL CAVITY: TUBERCLES IN LUNGS: CANCEROUS ENLARGEMENT OF GLANDS: CANCER OF LIVER AND PERITONEUM: NARROWING OF PYLORUS.‡ M., aged 54, a bookseller, was seen on November 28th, 1849. Six years previously, he had had an attack of hæmoptysis. The appetite then began to fail; sickness was felt after eating; and he had occasionally vomiting, which had increased in frequency. He had also had pain in the throat, and a sense of great constriction at the upper border of the sternum. He vomited blood, mixed with dark brown masses; not after eating, but generally in the morning, between three and five o'clock, and occasionally in the day time; and it was then preceded by a fit of coughing. Of late, he had lost flesh very rapidly. He vomited after meals, whether liquid or solid; and he also vomited florid blood, with dark clots and dark grumous masses. No cancer-cells could be distinguished. On November 23rd, he vomited half a gallon of florid blood, and on the next day even more. Great tenderness existed in the region of the stomach. A hard lobulated tumour was felt in the right hypochondriac region, measuring four inches transversely, and two inches from above downwards. He had had cough four months. There was dulness in the posterior and inferior part of the left lung. The pulse was 90, rather strong. The heart's impulse was rather increased, otherwise normal; he had palpitation occasionally. The urine deposited lithate of ammonia on cooling. Leeches were applied over the stomach. He vomited less, but the emaciation increased; and at times he vomited large quantities of florid blood. He died on December 15th.

The left pleura contained a pint and a half of blood, which had come through a laceration in the pleura, from an aneurism of the descending portion of the aorta encroaching on the left lung. The pericardium contained six ounces of serum, and the heart was contracted. Between the aorta and the œsophagus, two glands existed, greatly enlarged from cancerous infiltration, immediately projecting into a cancerous ulceration existing in the middle of the last named canal. The lungs contained tubercles. The liver contained a number of cancerous no-

dules, as also did the peritoneum of the diaphragm and the pelvis. The pylorus was contracted; and this, with the tumour felt during life, which consisted of a mass of cancerous glands, gave rise to the vomiting.

Harrington Square, London, October, 1853.

CHANCRE IN THE URETHRA MISTAKEN FOR GONORRHOEA.

ERRORS IN THE DIAGNOSIS OF A CHANCRE OF THE THUMB, PRODUCED BY ACCIDENTAL INOCULATION, AND FOLLOWED BY SECONDARY SYMPTOMS.

By JOSEPH SAMPSON GAMGEE, Esq.

In the month of February last, I was requested to see a patient with urethral discharge, by a friend who had been treating him for about a fortnight, to no purpose, with the ordinary remedies for gonorrhœa.

I found the glans uncovered, red, and swollen; the prepuce œdematous and also red; but their surface was otherwise dry and perfectly healthy. On pressure along the course of the urethra, a small drop of green thick pus appeared at its orifice. The discharge had from the first been very scanty. In the left groin was a lymphatic gland about three times the normal size. The last mentioned symptom, conjoined with the scantiness and viscosity of the discharge, the considerable amount of inflammation about the prepuce, and a knowledge of the fact that gonorrhœal remedies had proved of no use, led me to suspect the existence of chancre within the urethra; accordingly, on opening out its orifice, a small sore with greyish surface and bright red sharply cut edge was visible just within it.

Had the urethral sore healed before it came under my notice, the secondary syphilitic symptoms which would in all probability have succeeded, would have been attributed by the practitioner to gonorrhœa; and this would have added another to the list of badly observed cases invoked by the disciples of Hunter's doctrine (who hold the virus of syphilis and gonorrhœa to be one and the same) as proof of such identity.

As an additional guarantee of the chancreous nature of the urethral sore, a little of the pus from its surface was inoculated in the thigh, and here a well marked chancre was fully developed about the fourth day.

The primary and inoculated sores were destroyed with nitrate of silver, a mercurial course was prescribed, and the patient was cured within a month.

A few days after I saw this patient, I detected a little fissure at the end of my left thumb, close to the attachment of the nail; it became exquisitely painful, and sensibly affected the general health. It was only after treating it several days without success, that it occurred to me that in the manoeuvre necessary to see the urethral chancre (grasping the glans and separating the lips of the meatus with the ends of the thumbs), it was very likely that a little of the virus had got beneath the free margin of the nail, and there produced a chancre.

At this time, the thumb was much swollen; the sore at its end was covered with whitish adherent slough, except at the edge, which was bright red; the lymphatics on the palmar surface of the forearm, and inner surface of the arm, were corded, and their situation was denoted by red lines on the skin. Two friends, who had from the commencement favoured me with their advice, consented to my proposal to inoculate on the arm some of the discharge from the sore, and destroy it with nitric acid; with the double view of arresting the diseased local action, and ascertaining whether it were syphilitic, and mercurial treatment advisable.

The pain and swelling abated very considerably after the cauterisation, and nothing whatever appeared at the two spots on the arm, where the pus had been inoculated. The last fact was deemed proof of the non-syphilitic nature of the disease, and confirmatory of the opinion my friends had from the commencement entertained, that the sore was

merely dependent upon rather assiduous application, and consequent impairment of health.

When the eschar produced by the nitric acid separated, it left a weakly looking surface, which, in a few days however, improved, as did also the general health and the condition of the arm; the corded lymphatics having almost disappeared. But this was only a temporary change; the sore again became painful, and acquired its suspicious look, with whitish surface, red and sharp cut edge; moreover, it was now raised on a hardened base; the lymphatic cords on the forearm became very manifest; one of the axillary glands enlarged; and seven weeks from the origin of the sore, a well marked copper coloured roseola made its appearance on the palms of the hands and trunk. The problem was now solved, and the moment for decided action arrived. I destroyed the primary sore with strong nitric acid,* and commenced a mild course of mercurial treatment. After the lapse of another week, the skin affection had quite disappeared, the affection of the lymphatics almost so, and the sore had quite healed; but a good deal of induration remained at its base, and pathognomonic sores formed on both tonsils. Both these complications slowly but progressively yielded to corrosive sublimate and sarsaparilla, followed by iodide of potassium.

REMARKS. The study of this case suggests two facts for special consideration—the failure of the inoculation, and the error in not diagnosing the primary sore from its history and anatomical characters.

Were it not that the surgeon who performed the inoculation has frequently practised it successfully, the validity of the experiment might be questioned; but under present circumstances, the failure tends to lessen the value of inoculation, as a means of ascertaining the syphilitic character of a suspicious sore. But it is just to observe that almost invariably, the inoculation of the discharge from a primary venereal surface, does produce a chancre. Indeed, amongst a very large number of experimental inoculations of undoubted chancreous pus, I have only seen one failure besides my own case. That occurred in a young man, the subject of chronic phthisis; he had had a chancre at the frœnum for about three weeks, and it had destroyed a considerable portion of the glans. I performed three inoculations on the same patient with pus from the surface of the sore; they all failed. The primary sore healed after being twice cauterised with nitric acid. Any doubt as to its true syphilitic nature, was removed by the appearance in little more than another fortnight of syphilitic ecthyma in its most severe form.

Apart from experimental inoculation, there were, I now think, sufficient grounds for diagnosing the sore as syphilitic. The idea of my friends, that it was a common sore due to impairment of the general health by hospital work, had no better foundation than their kind hope that it should prove to be such; for it had none of the appearance, either at its commencement or during its progress, of the weakly sores that occasionally form about the pulps of the fingers and roots of the nails in weakly constitutions. Its bright red sharply cut edge, the white adherent slough on the surface, the burning pain, corded state of the lymphatics, the hardened base, conjoined with the fact that, just before its appearance, I had exposed myself to the risk of inoculating the thumb; that the general health was excellent; that when it failed, rest, fresh air, change of scene, and exercise, resorted to for its improvement, had no effect on the sore—appear to have been sufficient grounds for the

* I have been in the habit of giving chloroform in cauterising chancres; but my experience in this case, conjoined with the rather numerous accidents from this anæsthetic of late recorded, which suggest the propriety of only resorting to it when really necessary, and then with the greatest precaution, leads me to question whether in many of these cases the preventive is not as severe as the pain. Certain it is, that I suffered greatly from the chloroform for nearly thirty-six hours afterwards—great prostration, headache, and vomiting; but when, having determined upon the necessity of reapplying the nitric acid, I, in the absence of a friend, in a village on the banks of the Rhone, applied it myself, the pain was severe, it is true, but ceased in a few minutes; and whereas I had not rested for many nights, I fell off to sleep half an hour afterwards, slept soundly ten hours, and was enabled to resume my journey in comparative ease.

diagnosis. Repeated cauterisation until the specific character of the sore was destroyed, and a mild mercurial course, would have been prudent precautionary measures; at least, they would not have been productive of mischief.

Palazzo Corsi, Florence, Nov. 24th, 1853.

BIBLIOGRAPHICAL NOTICES.

MEMOIRS OF JOHN ABERNETHY, F.R.S.: with a View of his Lectures, Writings, and Character. By GEORGE MACILWAIN, F.R.C.S. 2 vols. 8vo., pp. 334 and 370. London: 1853.

THIS is an entertaining work; but we should have been better pleased with it, had it told us more than it does about its professed subject. We are not at all certain that the author is to blame for the meagreness of his details; but the question arises,—Was it necessary to expand his scanty materials into two octavo volumes by sparse printing, and the incorporation of foreign matter? We think that this might have been judiciously avoided. Perhaps, however, many readers may appreciate the work all the more, that it gives a narrative of some striking passages in the history of the pupil and biographer, as well as his sharp and free criticisms upon the abuses of the hospital system in London, and other real or supposed blemishes in the medical polity of the present day. For our own part, while, as critics, we are bound to condemn the discursive character of these volumes, and find fault with the attempt to give, in the form of a biography, matter wholly unsuitable to the legitimate plan of such a work, we must admit that the author is generally lively, earnest, and instructive. Nevertheless, as a biography, the book has not been correctly conceived. Complete success in biographical writing can only be attained by giving a narrative in which the hero is carefully kept in the foreground, and in which he is never veiled or removed from the reader by the interposition of the writer, or of any other monopolising person or thing.

JOHN ABERNETHY was born in Coleman Street, London, on the 3rd of April, 1764, or 1765. He was the second son of John Abernethy, a merchant, who traded under the firm of Abernethy and Donaldson, in Rood Lane, Fenchurch Street. The culture of his childhood was conducted at home; but, at an early age, he was sent to the grammar school of Wolverhampton, where he received the principal part of his education. He had a predilection for the bar; but, in 1779, his father apprenticed him to Sir Charles Blicke, a surgeon in large and lucrative practice, who then resided in Mildred's Court. Speaking of his apprenticeship, Mr. Macilwain remarks:—

"Diligent as he was, we suspect he found little during his apprenticeship, of those attractions which make labour and industry sources of pleasure and enjoyment. As a matter of course he would have been allowed to attend any lectures which were given at the hospital to which Sir Charles Blicke was surgeon, (St. Bartholomew's), and they would bring him in contact with Mr. Pott, who delivered a certain number of surgical lectures there. There were no courses of anatomical lectures given at St. Bartholomew's at that period; but anatomical lectures were delivered regularly at the London Hospital, by Dr. MacLaurin and Sir William Blizard, and afterwards by Sir William Blizard alone. As Sir C. Blicke lived in Mildred's Court and subsequently in Billeter Square, Abernethy would be about equidistant from the two hospitals, both of which he attended. We incline to think that it was in attending the lectures, and perhaps especially those of Sir William Blizard, that he first found those awakening impulses which excited in him a real love for his profession. It was about this time, we think, that he began to have more enlarged ideas of the nature and objects of surgical science; a state of mind calculated to enable him to thoroughly understand and appreciate Mr. Hunter, and to deduce from the principles which he was shadowing forth those relations and consequences which we shall endeavour popularly to explain: principles which, though originally directed to the treatment of so-called surgical maladies, were found equally to affect the practice of medicine." (vol. i, p. 45-7.)

At the London Hospital, Abernethy was in the habit of

preparing the subjects for lecture, which fitted him to enter upon the duties of a teacher at St. Bartholomew's with advantage, when that field was opened to him by the resignation of Mr. Pott as surgeon to that hospital. Sir Charles Blicke, assistant-surgeon, succeeded to Mr. Pott's position; and the vacancy created by the promotion of Sir Charles was filled up, on the 15th of July, 1787, by the appointment of Abernethy. The election was contested by several candidates: at last, it lay between Mr. Jones and Abernethy, when the former polled twenty-nine, and the latter fifty-three votes.

"As assistant-surgeon he had no emolument from the hospital: he had therefore a very reasonable inducement to set about doing that for which he felt himself calculated, and to which he had early directed his attention—namely, to teach his profession. The event showed that he had by no means miscalculated his powers. These proved well-nigh unrivalled. The appointment to St. Bartholomew's, besides other advantages gave him an opportunity of lecturing with the *prestige* usually afforded by connection with a large hospital. He did not, however, give lectures at the hospital at first, but delivered them in Bartholomew Close. There was at this time, in fact, no school, properly so called, at St. Bartholomew's. Mr. Pott gave about twenty-four lectures, which as short practical discourses, were first rate for that period. But there were no other lectures, not even on anatomy, which are essentially the basis of a medical school.

"Dr. Marshall, who was a very remarkable man, and no less eminent for his general ability than for his professional acquirements, at this time was giving anatomical lectures at his house in Bartlett's Buildings, Holborn. In a biographical notice of him in the *Gentleman's Magazine*, in which we read that he was giving lectures about the year 1787, it is incidentally remarked that "in all probability he derived little support from St. Bartholomew's Hospital; for recently, an ingenious young gentleman, Mr. Abernethy, had begun to give lectures in that neighbourhood. Abernethy, who seems to have been always seeking information, certainly attended some of Marshall's lectures; because he would occasionally refer to anecdotes he had heard there. He had thus attended most of the best lecturers of his day,—Sir W. Blizard, Dr. MacLaurin, Mr. Pott, and Mr. Marshall." (vol. i, p. 66-68.)

It would appear that Abernethy lectured with acceptance on anatomy, physiology, pathology, and surgery, notwithstanding an unconquerable "shyness". This shyness we find traces of in various parts of his life; and there seems to be no doubt of its having existed, however difficult it may be to reconcile it with that self-confidence and rude behaviour before patients for which Abernethy deservedly acquired a reputation: and to this, we may add, he owed some of his success. Abernethy's lectures became so popular, that it was at last necessary to provide better accommodation for his pupils.

"The governors of the hospital in 1790 determined on building a regular theatre within the hospital. It was finished in 1791; and Abernethy gave his October courses of anatomy, physiology, and surgery of that year in the new theatre. He had thus become the founder of the school of St. Bartholomew's, which for the approaches it made towards giving a more scientific phase to the practice of surgery, was certainly superior to any other. In expressing this opinion, we of course except John Hunter's lectures for the short time that they were contemporaneous with those of Mr. Abernethy; John Hunter dying in 1793." (vol. i, p. 78.)

After describing Abernethy's attainment of distinction and popularity as a lecturer, Mr. Macilwain enlarges upon the varied scientific pursuits in which he engaged. His *Essay on Lumbar Abscess* is deservedly praised; but we cannot think that Abernethy's treatment of cases of this description is so much "misunderstood" as his biographer supposes; but, even if it were so, we do not think that the proper method of removing this misunderstanding is by the introduction of a discussion regarding it in a work avowedly written for the general public. To enlighten the profession through popular works is to run the risk of being charged with an undue disparagement of the knowledge of our colleagues or competitors. Perhaps Mr. Macilwain has had the conduct of Abernethy too favourably before him when

composing this biography; for we find Abernethy's habit of quoting his book on the *Constitutional Origin of Local Diseases*, to those who consulted him, spoken of as only worthy of imitation; and we even likewise find a recommendation to adopt a more systematic method of writing medically for patients. We certainly do not concur with Mr. Macilwain's views, as expressed in the following passage:—

"Abernethy had a great deal more practice than he or any other man could do full justice to; finding it impossible to make people understand his views in the time usually allotted for consultation, he now referred his patients to his book, and especially to p. 72. This has been made the subject of a great deal of quizzing, and of something besides, not altogether quite so good-natured. For our parts, we think it the most natural thing in the world to refer a patient to a book which may contain more in full the principles we desire them to understand, than we can hope to find opportunity to explain at the time of consultation. We think that if asking a few questions and writing a prescription, (and we are here only thinking of a reasonably fair average time visit,) be worth a guinea, the explaining a principle, or so placing a plan before a patient, that his following it may be assisted and secured, is worth fifty times as much: and it came particularly well from Abernethy, one of whose lessons, and a most excellent lesson too, was the remark:—'That if a medical man thought he had done his duty when he had written a prescription, and a patient regarded his as fulfilled when he had swallowed it, they were both deceived.' As we are convinced that, *cæteris paribus*, success in medical treatment is indefinitely promoted by both patient and surgeon clearly understanding each other as to principles, we think it would be of great use if every medical man who has any definite principles of practice, were to explain them in short printed digests. Nay we have sometimes thought it would be useful to both parties, if in addition to the inquiries and advice given at consultation, a medical man should have brief printed digests of the general nature and relations of most of the well defined diseases: a careful perusal of one of these would help the patients to comprehend the nature and objects of the advice given, tend to the diffusion of useful knowledge, and in time help them to understand whether their treatment were conducted on scientific views, or was merely a respectable sort of empiricism." (vol. i, pp. 315-317.)

With the sentiments expressed in this extract, we trust that very few of our readers concur. For an educated surgeon or physician to appeal to his medically uneducated patients, as to whether their treatment be conducted on scientific views, is to open a wide door to quackery: it is, in fact, degrading the members of our profession to the level of homœopaths, hydropaths, and pill-venders, all of whom circulate "brief printed digests", as baits for money. In fact, if this "digest" system were tolerated, it would soon become as scandalous a method of professional advertising as that now carried on through the circulation of autobiographies. We feel assured that, when the evil tendency of the digest system is pointed out to Mr. Macilwain, he will perceive the propriety of cancelling, in future editions, the passage which we have now quoted.

Abernethy was married on the 9th of January, 1800, to Miss Anne Threlfall. He was a clumsy wooer, and a cold bridegroom. He conducted his courtship as a matter of business; and on his wedding day he lectured as usual at St. Bartholomew's.

In 1816, Mr. Lawrence was appointed Professor of Comparative Anatomy to the College of Surgeons, to the great satisfaction of Abernethy, under whose roof he had resided as a pupil for many years. Ere long, however, they became involved in a painful and protracted controversy, which is described by Mr. Macilwain. Lawrence taught views of life which were looked on as "sceptical": Abernethy earnestly opposed these opinions.

In 1815, Abernethy was appointed Surgeon to St. Bartholomew's Hospital, after having been assistant-surgeon for twenty-eight years. Mr. Macilwain with great propriety denounces the "hospital system", which causes men to wait so long in an inferior position. He was fifty years of age before he was made surgeon, and acquired, in virtue of that position, "an opportunity of taking an active share in the practical administration of the hospital". Hard work

had then told upon him, and the elasticity of youth was gone. Mr. Macilwain says:

"He complained in 1817 of the fatigue of the College Lectures, coming as they did on the completion of a season of the 'mill-round of hospital tuition and practice.' So that, when we mentioned the period of his lectures at the College as on so many accounts the zenith of his career, there was the serious drawback arising from a certain diminution of strength which had never been at best equal to the physical fatigue of his multiform avocations." (vol. ii, p. 214.)

In 1817, Abernethy resigned his professorship at the College of Surgeons; and, on the 15th of July of that year, he received from the "Court of Assistants" of the College the following vote of thanks, by which he was much gratified.

"Resolved unanimously.—That the thanks of this court be presented to John Abernethy, Esq., for the series of lectures delivered by him in the theatre of this College in the years 1814, 1815, 1816, and 1817, with energy and perspicuity, by which he has elucidated the physiological and pathological opinions of John Hunter, explained his design in the formation of the Hunterian collection, illustrated the principles of surgery, and thereby has highly conducted to the improvement of anatomical and physiological knowledge, the art and science of surgery, and to the promotion of the honour of the College." (vol. ii, pp. 322-323.)

In July 1829, declining health caused him to resign his seat at the Examination Board of the College of Surgeons. He died on the 20th of April, 1831. His body rests in the parish church of Enfield, where a plain tablet has been inserted in the wall over his grave.

There can be no doubt that Abernethy possessed uncommon natural talents, and that they were well disciplined and cultivated. His judicious maxims tended to give a wholesome bias to the practice of medicine and surgery; and he undoubtedly deserves an honourable place among those who have assisted to advance medicine from an empirical art to a science based on principles. To Abernethy, then, we would pay the willing homage of admiration and gratitude; but, in doing so, we do not think it necessary to award to him higher attainments in science than those possessed by many of his successors of the present day. There is no truth in a remark which is current in society, that in our day there are no Abernethys and no Astley Coopers. The very opposite of this proposition is absolutely true; for, in place of one Abernethy or one Astley Cooper, we have several in most of our large towns, and, in London and the larger cities, they can be reckoned up in hundreds. The elevation of the great body of the profession, consequent upon the Act of 1815, makes it almost impossible for any medical man to tower majestically over his fellows, as was done in former times. The timid and ignorant apothecaries, who, in virtue of their own shortcomings, had consultations as often as possible, have almost been swept away by the advancing tide of education; and they have been succeeded by a legion of accomplished practitioners, who have won the public confidence, and who, in place of being the mere agents of a superior order, hold themselves to be, and indeed are, competent to grapple with all emergencies. This new order of men manfully resent as an injury to the public the attempt of the College of Surgeons to perpetuate, by extreme laxity of examination, a very inferior grade of practitioners, while from the fellows (the superior grade) they demand higher attainments. In these facts lie the explanation of the circumstance, that while there is an enormous increase in the number of first-class practitioners, there are nevertheless scarcely any physicians or surgeons or general practitioners, who commandingly overtop the rest. This state of things is not an unmixed good. In consequence of the old avenues to fame and fortune being nearly closed, our ambitious youths are driven to sad expedients, and are too often tempted to make shipwreck of their finer feelings, by advertising themselves in connexion with portraits, autobiographies, homœopathy, secret methods of cure, and pseudo-charitable dispensaries. In the hope of getting a living out of the remaining fragments of the ancient feasts of fees by which the older physicians and pure surgeons were regaled, modern aspirants to "pure" and

"special" practice, resort to methods and schemes which cannot be defended. Our only hope is that, as the evils to which we refer have nearly reached their climax of offensiveness, we are (if we may so express it) entitled to look for early amendment. The fact will assuredly at last command attention,—that in consequence of the elevation of the whole profession to a higher platform, the prizes must of necessity be greatly divided: the fame and the fortune of an Abernethy must be broken into many different allotments of fame and of fortune, wherewith to reward a host of urgent and often worthy claimants. It is wise to ponder well these signs of the times; for changes are coming.

We must curb an inclination to follow Mr. Macilwain in his interesting reflections: for them we must refer our readers to the volumes now before us. It is want of time and space, and not of inclination, which causes us here to terminate this notice. Were we fully to enter upon the subjects which the author introduces to our notice, we might easily fill many columns with the discussion of topics of supreme importance in medical science, medical practice, and medical polity. Notwithstanding the blemishes of this work, we think that it is one which will well repay perusal.

THE DECLINE OF LIFE IN HEALTH AND DISEASE; being an attempt to Investigate the Causes of Longevity, and the best means of attaining a Healthful Old Age. By BERNARD VAN OVEN, M.D. 8vo., pp. 300. London: 1853.

DR. VAN OVEN'S work, in its plan and material, bears some resemblance to Hufeland's *Art of Prolonging Life*, and to Dr. Day's work on the *Diseases of Old Age*. It is, however, not simply a copy from these and other treatises; but is a digest of what has been previously written and collected by others, combined with the original reflections and experience of the author. Dr. van Oven introduces himself to his readers in a preface, in which he mingles a description of his qualifications to teach with much becoming modesty. He says:—

"The celebrated Heberden remarked, that the life of a physician should be like that of a vestal virgin, which was divided into three periods: in the first of which she learned her profession, in the second she practised it, and in the third she also taught it to others. I have certainly passed through the first and second of these periods: after several years employed in the study of my profession, I have spent thirty-five years in the practice of it; and, anxious to fulfil completely my vocation, I desire, before I quit the stage, to strike one blow for the good cause, to do something, however slight, to improve the sanitary condition of mankind, to alleviate pain, and oppose the influence of disease. I cannot hope, strictly speaking, 'to teach my profession to others'. The important task of instructing the rising generation of students is most properly committed to a class of men, who, themselves trained to their duties, perform them in a most able and efficient manner; and any one even slightly acquainted with the medical profession thirty or forty years since, and who will compare its condition then with its present state, must bear testimony to the vast improvement which has taken place."

Dr. Van Oven's work is divided into three parts, and an appendix. The first part treats of the "Decline of Life in Health." It contains a sketch of the progress of the organisation of man, from birth to maturity; and special observations upon maturity and the decline of life.

In the second part "Longevity" is considered, with reference to its causes and mode of attainment.

"The Decline of Life in Disease," forms the subject of the third part. The following subjects are considered:—the climacteric period in both sexes; the diseases of age; particular diseases, such as gout, cancer, apoplexy, gangrena senilis, prurigo senilis, tussis senilis, etc.

The appendix contains some interesting statistical tables of persons who have attained ages from 100 to above 150. As the author admits, there are obviously "many errors, and exaggerations, and perhaps some wilful misstatements" incorporated in his tables; but he says: "After having

made a due allowance for all these, enough and more than enough will remain to justify a fair presumption, that human life might endure much longer than it usually does, and to encourage the exertions of those who desire to promote healthful longevity. (p. 277.)

SCIENCE OF HEALTH. By STEPHEN H. WARD, M.D. London: 12mo., pp. 412. London: 1853.

THIS is a very good popular exposition of hygienics. The philosophy of the subject is so abundantly illustrated by facts, as to render the book interesting and instructive to young persons and others unacquainted with physiology. Two short extracts are subjoined.

"COMMON SALT—chloride of sodium, as the chemist calls it—is supposed to furnish by its decomposition the muriatic acid which plays so prominent a part in digestion, and soda, which gives an alkaline character to the bile: it also forms one of the constituents of the blood, and seems essential to different vital processes. It is derived from animal food, milk, and some vegetables. From its importance to, and from the quantity required for the purposes of the animal economy, it is usually added in the free state to animal and vegetable food. Salt is found to be a necessary part of the food of domesticated animals; and many wild animals have been observed instinctively to seek it. Every one has heard of the salt springs in North America, to which the term 'licks' has been applied, in consequence of the wild animals, the deer, and buffalo, resorting to them, and licking the impregnated earth in their vicinity. Karsten, a German writer, says that common salt has generally become a very great necessity, even for the rudest nations. In not a few countries, it is one of the most valuable mercantile commodities. In several countries of Africa, men are sold for salt . . . in the district of Acera (Gold Coast), a handful of salt, the most valuable merchandise after gold, will purchase one, or even two slaves. Mungo Park mentions, that among the Mandingoes and other negro tribes in the interior, the expression, 'he flavours his food with salt', is synonymous with that of 'he is a rich man'. Park experienced, from the necessity of giving up the use of salt, especially when long confined to vegetable food, a longing after salt, such as he was unable to express in words." (pp. 244-245.)

"MOLLUSKS. Of those used for food, oysters enjoy the greatest repute. They are to be procured in the vicinity of the coast in most seas, and are generally found a little below the surface of the water, attached to rocks, stones, or the roots of trees, or lying free upon banks. They are removed to reservoirs or beds, or to creeks, into which the tide flows, and kept for some time, before they are considered in fit condition for the market. The art of thus parking oysters seems to have been familiar to the Romans; and the invention, if such it may be considered, is ascribed by Pliny to Sergius Orata: the oysters of the Kentish coasts were indeed in repute with Roman epicures soon after the invasion by Cæsar. The flavour of oysters is delicate and much admired, and these mollusks have the merit of being well fitted for those of weak digestion. Raw oysters are digested in rather less than three hours, while stewed oysters take three hours and a half to digest. The latter are not only coagulated by heat; but the butter used in cooking them adds to the indigestibility. Mussels and cockles are used as food, but chiefly by the lower classes; they are difficult of digestion, and frequently give rise to nettle rash and other disagreeable symptoms. Mollusks of different kinds form an important part of the sustenance of many savage island tribes, particularly of the natives of Terra del Fuego, and other parts where a higher order of nutriment is scarce. The snail is eaten, and pickled for exportation, in some of the cantons of Switzerland. Dunglison says:—'It was an article of luxury among the Romans. Fulvius Hirpinus, not long before the civil war between Cæsar and Pompey, made several snail parks in his garden, keeping every variety distinct. He had the white snails of Reate, the grey and large snails of Illyricum, the fruitful snails of Africa, and the Solitan snails, regarded as the most famous and excellent of all. They were fed upon a pap made of sweet wine, honey, and flour; and under this diet they became so wholesome and delicate, and were so much esteemed, that they were sold for eighty quadrants the dishful. The white snails are eaten in many places, and are all perhaps wholesome. They are gelatinous and viscid, and are frequently swallowed raw. In this way they have been recommended as a nutritious aliment to consumptive individuals.' (pp. 266-267.)

REPORTS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON.

NOVEMBER 26TH, 1853.

FORBES WINSLOW, M.D., D.C.L., President, in the Chair.

FIBRINOUS PLUGS IN VEINS. BY HENRY LEE, ESQ.

Mr. LEE exhibited the preparation of a case in which the profunda femoris vein, with its branches, was plugged with a mass of fibrin. This had resulted from the introduction of purulent matter into the blood from an abscess on the inner side of the thigh. He detailed certain experiments performed by M. Gaspard, who injected into the right jugular vein of a dog two and a half ounces of thick fetid fluid, derived from the maceration of cabbage leaves in water. Death occurred during the following night.

On *post mortem* examination, the lungs were found of a dark colour, with some black patches, but still crepitant. The left ventricle of the heart presented brown stains; its internal surface was of the colour of lees of wine. The right ventricle contained a hard fibrinous concretion, two drachms and a half in weight, of a light yellow colour, and having the external appearance of grease. It was of the same consistence throughout, and was free at all points, except a small portion which was attached to an inflamed spot on the inner surface of the ventricle. No appearance of the injected fluid could be detected in the clot; it was prolonged into the pulmonary artery, vena cava, vena azygos, axillary vein, and even into the right jugular vein.

Dr. ROUTH remarked, that putrid pus had been injected into rabbits without injury, and that wounds from dissection are usually innocuous. The results mentioned by Mr. Lee must arise from other circumstances, as those of epidemic influences and bodily weakness. Hectic fever does not usually follow the introduction of pus within the system.

Dr. MACKENZIE agreed with Mr. Henry Lee on the question of the obstruction of veins by fibrinous deposition from a vitiated condition of the blood. He did not speak specifically of a vitiated condition of the blood from pus, because this, being a fluid which varied very greatly in its properties, would give rise to very different results in different cases. Speaking, however, of vitiation of the blood generally, he could affirm that, from this cause alone, arrest, stagnation, and coagulation of the blood might take place in the veins, without any primary inflammation of their coats. That some alteration of their lining membrane was induced by the vitiating matter, he had no doubt, although it was difficult to define its precise nature; and he believed that, in consequence of this alteration, the blood, instead of flowing onwards, was arrested and coagulated in the veins. Upon this arrest and coagulation the general phenomena of phlebitis ensued.

INTERNAL METRITIS AND UTERINE CATARRH. BY E. J. TILT, M.D.

Dr. TILT contended, that to subacute inflammation of the mucous membrane of the neck of the womb the term uterine catarrh should alone be applied; by giving it to acute inflammation of the neck, French pathologists had been led to use dangerous injections into the cavity of the womb. Subacute inflammation of the mucous membrane lining the womb was characterised by the usual uterine pains and hysterical phenomena, and by inconsiderable swelling, if any, of the cervix, which was sometimes only painful on lateral pressure, the discharge being rarely muco-purulent, generally mucous, and sometimes sanious. In addition to the known means of treatment, Dr. Tilt advocated the topical application of tincture of iodine to the inner and outer surface of the womb, to be repeated every four or five days. Acute inflammation of the mucous membrane of the body of the womb could not be distinguished from the inflammatory affections of the whole organ; but, in some cases of menorrhagia, this mucous membrane was alone affected, and threw off a false membrane, different from the decidua membranes which have been hitherto described. Dr. Tilt exhibited a morbid specimen, taken from a young woman who died of menorrhagia under Dr. Watson. He thought that future researches would show that there was a chronic inflammation of the body of the womb, in most cases of dismenorrhœa accompanied by exfoliation of the mucous membrane. He then described a form of internal metritis, to which he gave the name of hæmorrhagic, to mark the symptom by which it was habitually accompanied. He illustrated it by a case in which astringent injections, cauterisation of the neck of the womb with the nitrate of silver, as well as internal remedies,

were without avail; whereas, when large doses of morphine, two grains *per diem*, were given to allay pain and calm hysterical symptoms, the sanguineous and semi-purulent discharges were checked, and the patient recovered. Another variety of internal metritis was characterised by the growth of fibro-plastic vegetations on the surface of the womb; these vegetations giving rise to sanguineous discharges and severe uterine symptoms. Dr. Tilt deprecated the use of uterine injections, on account of the uncertainty of their action, either in a similar set of cases, or even in the same patient—admitting, however, that they might, perhaps, be useful in some cases of the fibro-plastic variety. In that disease he recommended the careful introduction of Recamier's curette, a uterine sound a little larger than Dr. Simpson's, somewhat curved at its extremity, and hollowed out under its curvature, so as to remove the vegetations by gentle abrasion. Dr. Tilt had also found this instrument very useful in removing portions of retained placenta, the presence of which were indicated long after parturition, by flooding, by an enlarged body of the womb, and by uterine symptoms. He also showed another large instrument, which had been used by Recamier for the same purpose as the smaller, when the internal neck of the womb was widely dilated by inflammatory action—a circumstance of rare occurrence. He had found another plan of treatment successful in one case of the fibro-plastic variety; viz., after the application of the speculum, to introduce into the cavity of the body of the womb Dr. Simpson's uterine sound carefully surrounded by cotton-wool, saturated with tincture of iodine. The vegetations came away with a sero-purulent discharge after a few days; the operation was repeated, and the patient was in a short time relieved of a sero-sanguinolent discharge, which had lasted for years. Dr. Tilt inferred that tincture of iodine and iodide of iron were the topical applications from which practitioners would derive the greatest assistance in the treatment of uterine diseases.

Mr. STREETER (holding up the large curette invented by Recamier, and exhibited by Dr. Tilt) asked if it was really intended to be introduced into the uterus? It was a most dangerous instrument; and he did not think that it could be introduced, a few days after delivery, for the removal of retained portions of placenta.

Dr. HENRY BENNET did not understand why the mucous membrane of the neck of the uterus was more prone to inflammation than that of the body of that organ. He had rarely met with the latter disease, but believed that it would be indicated by exalted sensibility of the organ, enlargement of the cavity, a patulous os uteri, a sero-purulent or bloody discharge, and a marked reaction on the health. The mere presence of hæmorrhage, or of fibrinous casts, would not prove its existence. The treatment of inflammation of the mucous membrane of the canal of the cervix is simple and effective, while that of the body is beset with difficulty and some danger. He had known the introduction of a bougie to dilate the canal not only give intense pain, but induce abscess of the broad ligaments. He had employed the nitrate of silver and the acid nitrate of mercury.

Dr. GREENHALGH believed that uterine catarrh is due to inflammation of the mucous membrane both of the body and of the canal. In the acute forms of the disease, he would employ the hot-bath, with mercury and Dover's powder; and in the chronic states he would direct change of air and improvement of the general health. He would not affirm that the application of potassa fusa and other local remedies was always improper, but he believed it to be rarely called for. As a rule, he objected to much local interference.

Dr. MACKENZIE was persuaded that the anatomical seat of uterine catarrh was exclusively the cervical canal, and the numerous mucous follicles with which it was studded, rather than the mucous membrane of the body of the uterus. So confident was he on this point, that he would venture to assert that all mucous discharges proceeding from the uterus had their origin in the cervix, and all sanguineous or sero-sanguinolent discharges in the lining membrane of the body of the uterus. Some time ago, he had the opportunity of making several observations upon this membrane in a case in which the uterus was inverted; and he had observed that, whilst it was constantly covered with a sanguineous fluid, no mucus was ever exuded from it; and that, under the influence of mechanical irritation, blood and not mucus was thrown out from it. With regard to internal metritis, and the dependence of uterine catarrh upon inflammation of the cervix uteri, he had great doubt as to the accuracy of some of the opinions which had been expressed by Dr. Tilt.

Internal metritis, in the ordinary sense of the word, he regarded as very rare; and he thought that the immunity of the lining membrane of the uterus from inflammation might be explained by a reference to its anatomical and physiological characters. On the one hand, it was extremely vascular; and on the other, its function being that of separating periodically a certain amount of blood from the system, or something very analogous, and free transudation of blood would take place, and so remove that congestion which was a primary and essential condition of the inflammatory process. The preparations shown as instances of false membrane exuded from the lining membrane of the uterus, as a consequence of inflammation, did not, in his opinion, support this view of their origin. The supposed false membranes appeared rather to be derived from blood which had been poured out into the uterine cavity, and which, having lost its fluid and coloured portions, had become moulded into the shape of the body and neck of the uterus—changes which had no more connexion with uterine inflammation than had the fibrinous concretions often found in the heart and great vessels with inflammation of these organs. Uterine catarrh, also, in his opinion, had no necessary connexion with inflammation of the uterine neck. It was essentially hypersecretion of the mucous follicles of the cervix; and, as such, might have its origin in any of those deranged states of the constitution and of the nervous and vascular systems by which the nutritive and secretory functions generally were liable to be modified or affected. Some time ago, he had a case which illustrated these views, as well as the relative value of constitutional and local treatment; and which clearly indicated that profuse uterine catarrh might occur without any inflammatory lesion of the cervix; whilst the inefficacy of local, as compared with constitutional treatment, was forcibly shown.

SATURDAY, DECEMBER 3RD, 1853.

FORBES WINSLOW, M.D., D.C.L., President, in the Chair.
EXOSTOSIS ON THE CRANIUM OF AN EPILEPTIC PATIENT.

BY DR. GIBB.

Dr. GIBB exhibited a portion of a parietal bone which had a small exostosis on the inner surface. It had been taken from a woman, aged 40, who had been epileptic from the age of 15. She died in the hospital at Montreal, four days after being admitted labouring under delirium tremens. The symptoms of the latter disease were strongly marked; and she also had epileptic attacks three times on each day of her stay in the hospital. The dura mater appeared quite healthy throughout.

PATHOLOGY AND TREATMENT OF SWELLED TESTICLE.

BY J. L. MILTON, ESQ.

The author had not found neuralgia, tubercle, or carcinoma, as the result of orchitis; all he had found were the common proceeds of inflammation, and he believed that neglected orchitis very often impairs the functions of the testicle. A long time after a so-called cure, the epididymis had been found hard, and, after death, examinations of the testicle, where a similar hardness could be felt through the scrotum, showed induration of the epididymis, contraction, etc. Mr. Holmes Coote had also found the vas deferens contracted, and its walls softened. The author then examined the various theories of the origin of orchitis from gonorrhœa, and rejecting those of metastasis and an erratic disposition of the gonorrhœa towards its decline, he observed that there were no proofs of the doctrine of sympathy; speaking of a case, in which the extremities only of mucous canals became inflamed, Mr. Milton thought that extension of the inflammation took place in every case. The absence of pain in the intervening parts might be owing to their lower organisation; Sir A. Cooper had shown that the inflammation was milder in the lower part of the urethra. Orchitis does not arise when the gonorrhœa is most intense, but when the inflammation has had time to spread backwards. He doubted whether orchitis arose from injecting stimulating medicines.

Mr. Milton suggested treatment by means of preparations of potass and graduated injections. In upwards of six hundred cases of gonorrhœa treated thus, three only had been attacked with orchitis, and in these the treatment had not had a fair trial; he thought antiphlogistic treatment useless, and preferred half-grain doses of morphia and acetate of ammonia, with blistering on the second or third day. He applied hot water to the scrotum, and allowed nutritious diet and stimulants in moderation.

A discussion followed, in which Dr. de Meric, Mr. Hancock, Mr. Dendy, Mr. Weedon Cooke, Mr. Acton, and other gentlemen took part. In the course of the discussion,

Dr. GIBB said that he had seen orchitis treated in the hospital at Montreal by an ointment containing one grain of biniodide of mercury in ten grains of lard. The time required for cure was from twenty-four hours to three days. He had himself employed this plan in two cases with success.

FORBES WINSLOW, M.D., D.C.L., President, in the Chair.

FIBRINOUS CONCRETIONS IN THE HEART OF A MAN WHO HAD ATTEMPTED SUICIDE BY HANGING. BY B. W. RICHARDSON, ESQ.

Mr. RICHARDSON exhibited some specimens of fibrinous concretions, taken from the heart of a man who had attempted suicide by hanging. The patient was a tall man, a resident in Mortlake, who on Wednesday, November 30th, suspended himself in a narrow passage, in such a position that the cord did not press on the trachea. He remained suspended for, it was believed, at least a quarter of an hour. When cut down, life was not extinct. After some time, respiration and circulation returned; but there was complete anæsthesia. After some hours, the circulation and respiration were much above the healthy standard; and on the following Friday he died, with "typhoid" symptoms. On examining the body, along with Dr. Willis, Dr. Cormack, and Mr. Brown, Mr. Richardson found firm coagula of fibrin in both the right and the left cavities of the heart, and stretching into the vessels. The brain was much congested; and there was considerable effusion in the arachnoid.

NEW FORCEPS FOR APPLYING LIGATURE TO ARTERIES.

BY DR. DE MERIC.

Dr. DE MERIC exhibited a forceps which had been referred to him by the Council. It was the invention of M. Apostolides, a Greek medical student in Paris. There was an apparatus by which, a noose having been first formed and placed on the forceps, the ligature was pushed down over the artery, and then tied.

MODERN PHILOSOPHY OF CANCER. BY ROBERT DRUITT, M.D.

[This paper will be published as an original communication in this JOURNAL.]

In the discussion, Messrs. Richardson, W. Adams, Pilcher, Weedon Cooke, H. Smith, and Drs. Semple and Snow, took part. Several of the speakers agreed as to the propriety of rejecting the term malignant.

MONDAY, NOVEMBER 12TH, 1853. [PHYSIOLOGICAL SECTION.]

W. TYLER SMITH, M.D., Vice-President, in the Chair.

ON THE COLOURING MATTER OF THE BILE.

BY EDWARDS CRISP, M.D.

Dr. CRISP exhibited numerous specimens of dried bile, taken from various classes of vertebrate animals. His object had been to examine the correctness of the doctrine advanced by Kölliker, that the colouring matter of the bile is formed from the *débris* of blood-corpuscles, which had been destroyed by the spleen. He had found that this view was negated, by the fact that removal of the spleen did not affect the colour of the bile in the manner which would be expected from this theory. In fact, the bile was of a deeper colour in a dog from which the spleen had been removed, than in another in which that organ had been allowed to remain.

NEW COPPER TEST FOR SUGAR IN ANIMAL FLUIDS.

BY C. D. GIBB, M.D.

Dr. GIBB was accustomed to test for grape sugar in animal fluids, by adding from half a grain to two grains of black protoxide of copper, then pouring in liquor potassæ, and boiling for two or three minutes. The liquid turned of a more or less cherry colour, with evolution of oxygen, and the red suboxide of copper was precipitated. The test is very delicate.

MODUS OPERANDI OF NARCOTICO-IRRITANTS. BY JOHN SNOW, M.D.

Dr. SNOW said that all narcotics were more or less irritants, causing redness and heat in most cases when applied to the skin, and general excitement when absorbed in the blood. It was the opinion of many physiologists that these agents acted as stimulants in the first instance, and produced their narcotic effects by exhausting the sensibility; but this view was untenable, first, because the stimulant effects were often absent altogether, and when present they bore no relation to the amount of stupor which might follow; secondly, because excitement often appeared again in the process of recovery, when the insensibility passed off; and lastly because, in the use of volatile narcotics, the coma could be continued or allowed to subside at pleasure, by merely keeping up or leaving off the inhalation, which proved that the excitability was merely suspended, and not exhausted. The connexion between the irritant and the narcotic effects of medicines was of a very close nature, although it was not one

of cause and effect. He considered that both the irritation and the narcotism were caused by one power in the agent applied, namely, the power of diminishing oxidation in the living body. A number of reasons were given to show that narcotics have the power of diminishing and preventing the process of oxidation, on which sensibility, contractility, and the other animal functions, depend. The following are some of them. The amount of carbonic acid gas produced in respiration has been found to be diminished by certain narcotics, as alcohol, ether, and chloroform. The colour of the venous blood is lighter than usual in patients under the influence of the two latter agents, showing a diminution in the changes which take place in the systemic capillaries. When animals are killed in the space of about five minutes by narcotic vapours, the chief symptoms and phenomena are the same as in asphyxia by privation of air. The greater number of narcotics have the effect of preventing combustion, putrefaction, and other forms of oxidation out of the body; their power as antiseptic, etc., bearing a direct relation to their power as narcotics, when they resemble each other in their chemical constitution.

Whilst the diminution of oxidation in the system produced narcotism directly, it indirectly caused irritation, by inducing congestion in the capillaries and small arteries, where sufficient vascularity existed. Dr. Alison, Dr. John Reid, and various others, had shown, by facts which he enumerated, that the circulation through the capillary blood-vessels is assisted by the various changes of composition, etc., taking place in the neighbourhood of these vessels, the chief of which consisted in a process of oxidation. When this process was diminished, the flow of blood through the capillaries was impeded, and these vessels and the smaller arteries become congested, causing the redness and other phenomena of irritation. It was in the most vascular organs, and in persons having most blood, that irritation and excitement were most frequent. Microscopic observations had shown that the circulation through the capillaries was impeded or stopped by the action of opium, carbonic acid gas, and some other narcotics. Narcotico-irritants did not increase either the mental or bodily powers of persons in perfect health, in whatever doses they might be administered; but a small quantity of wine or opium often gave temporary energy to those who were in a state of debility. In such persons, what blood they had loitered chiefly in the large veins, and a slight obstruction to the capillary circulation caused the blood to accumulate a little in the arteries, and the heart was impelled to increased action to overcome the resistance. Under such circumstances, the better supply of blood to the various organs more than compensated for the true narcotic action of the agent employed. From the continued presence of certain narcotico-irritants in the blood for a long period, as in Bright's disease of the kidneys, the left ventricle of the heart often became hypertrophied by its efforts to overcome the resistance to the circulation through the capillaries. It had been lately stated, that the poison which sometimes caused coma and convulsions in this disease was carbonate of ammonia, arising from the decomposition of urea in the blood; and some experiments he had performed on gold fishes showed that carbonate of ammonia was a much more powerful poison than urea.

In the discussion which followed, Mr. Richardson, Drs. Cogswell and Sibson, and other members, took part.

EPIDEMIOLOGICAL SOCIETY.

B. G. BABINGTON, M.D., President, in the Chair.

MONDAY, DECEMBER 5TH, 1853.

THE INDIAN PLAGUE AND THE BLACK DEATH. (COMMUNICATED BY J. O. M'WILLIAM, M.D.) BY AUGUST HIRSCH, M.D., OF DANTZIC.

The author stated that in the whole history of epidemics, there are few epochs more interesting than that of the fourth decennium of our century; for then, within a few years, we find many most important diseases spread epidemically over the globe. These were preceded by agues, which prevailed at the close of the third decennium, and by the influenzas of the years 1831-33. Cholera, which in 1823 had stopped short on reaching the frontier of Europe, overspread with the force of a torrent the Russian empire, and in 1831 entered Germany, where, in the southern parts of the kingdom, it was soon followed by typhoid fever and dysentery. At the same period "sweat fever" appeared in France and Italy, and, for the first time "typhus cerebri" was propagated epidemically. In North America cholera, typhus and yellow fever, raz . Turkey, Western

Asia, Egypt, and the greater part of North Africa, were ravaged by typhoid fever and Oriental plague.

It was just at that period that a disease of a new and most malignant character broke out in the north-west part of Hindostan. Research among the archives of the Medical Board, however, made it evident that the same disease prevailed some years before in those regions; but the attention given to it had subsided soon after the epidemic ceased. The author considers the disease in question to have been a very decided plague, specifically modified; and that, in order to distinguish it from the Oriental plague, it may justly be denominated the "Indian Plague." The first historical report of the outbreak of the Indian plague dates from the year 1815, in the provinces of Kutch and Guzerat, which in the previous year had suffered from terrible famine. Neither the origin nor the course of the epidemic could be distinctly traced, but there is no doubt that the disease already, in May, 1815, had spread over some parts of Kutch, and the district of Wagoor; that it raged in these territories until the following year, and made great havoc among the inhabitants. At the same time the epidemic appeared in Kattywar, whence it spread to Scinde, and in November it reached Hyderabad, where from 60 to 70 persons daily fell victims to the plague. The epidemic entered the north-eastern district of Guzerat in the beginning of 1817, and abated in the fall of the year. With the rainy season of 1819 it burst forth with new vigour, and overspreading the territory which had suffered during the previous year, reached the northern part of Guzerat, and in the east the Zillah of Ahmedabad. With the close of 1821 the epidemic everywhere disappeared; and except the remark of Dr. Rankine, that the plague had been observed in 1823 in the mountainous territory of Kamoon, we have no information of its re-appearance until 1836, when it broke out with great malignity in a country far removed from that above-mentioned. It was then that the disease for the first time attracted general attention, and gave rise to scientific inquiries, and the adoption of sanitary measures. The Radjpootana States were the scene of the ravages of this epidemic; and as the first Report of the disease came from Pali in the province of Marwar, it has obtained the name of the Pali plague, although it is anything but certain that the epidemic originated in that place, for it also raged at the same time (July, 1836) in other districts of that province. After having traversed the greater part of Marwar, the disease passed the chain of hills separating the eastern borders of this province from Meisar, overspread that country, and afterwards the district of Adjmer. Early in 1837, when the epidemic in Marwar had nearly ceased, it appeared in Misserabad, and declined with the rainy season. At the close of 1837, it again invaded Marwar, especially the town of Pali, and continued till the spring of the following year. Since that time, up to 1850, there is no further report of the prevalence of the malady. It was in this year that a fresh outburst occurred at Ghurevhal and Kamorn, in the Himalayan territory. Dr. Hirsch gives a very minute and graphic description of the mode of invasion, and of the general symptoms of the disease. The disease, although a bubonic plague, was distinguishable from the Oriental plague by an attendant pulmonary affection, with hæmoptoe. The mortality was dreadful; the supposition that it was from 75 to 80 per cent. of those attacked being by no means exaggerated. In the town of Pali alone, in a population of 20,000 inhabitants, 4,000 persons fell a sacrifice to the plague in the period of seven months. The disease did not appear to be contagious, nor was it at all influenced by season.

The author adduced strong evidence as to the identity of the Indian plague with the black death of the fourteenth century, which Hecker and other writers had shewn to be a bubonic plague, combined with an affection of the lungs.

Dr. JAMES BIRD had not actually seen the disease; but after a careful examination and comparison of the various accounts to be found in the reports of the Bombay and Calcutta Medical and Physical Societies, and from information derived from other sources, he was satisfied that this Indian disease is a form of sporadic plague, propagated by pulmonary imbibition in the high-walled, crowded towns of India, and not communicated like the ordinary epidemic plague of the Levant, which required malarious influences for its propagation. Dr. Bird had seen cases of plague occurring sporadically in Upper Egypt, when the disease was not epidemic. The natives did not consider this form of the disease infectious; they handled the dead and sick with impunity, and they confidently asserted that it would not spread.

Dr. M'WILLIAM wished to ask Dr. Bird whether attention had been drawn to the conditions under which the disease spread in

India. In Egypt the plague was annihilated both by high and low temperatures, and only spread when the heat was moderate. Did a similar law prevail in India?

Dr. MILROY considered that this paper clearly showed that true plague of the Levant had appeared in India, and that *spontaneously*; for its appearance in an island instead of a maritime district seemed to exclude the possibility of its having been conveyed from the Levant. It was very important to bear this fact in mind, as it shows that this and similar diseases may develop themselves in different countries spontaneously. The fact of the occurrence or absence of hæmoptysis was not a sufficient ground for a distinction between the two diseases. It arises from the same cause as the black vomit of yellow fever, viz., congestion of the capillaries, in the one case of the stomach, in the other of the lungs. Nor is the absence or presence of infection any ground for a distinction. Plague was not nearly so contagious as is generally supposed, and the sporadic cases could easily be explained by the crowded and filthy houses in which the natives live. Attention should be drawn to the simultaneous appearance of plague, cholera, typhus, etc., in different parts. Probably, at certain times, a malarious influence spreads over the whole globe, and causes different forms of disease in different parts of the world.

Dr. J. BIRD, in answer to Dr. McWilliam, observed, that in Egypt the plague disappeared after St. John's day, when the weather became dryer; but he was not aware that any similar law was known to hold in India. He concurred with Dr. Milroy in thinking these different epidemics essentially the same, and varying only in the circumstances in which they occur.

Dr. SNOW observed, that the plague was most prevalent at Gourlah when the temperature was moderate—between 60° and 70° Fahr.; but that cases were also known in cold and in hot weather, as was occasionally the case in Egypt.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

SESSION XXXIII. SECOND MEETING.

WEDNESDAY, DECEMBER 7TH, 1853.

JAMES Y. SIMPSON, M.D., President, in the Chair.

The following officers were elected; *President*: James Y. Simpson, M.D., Professor of Midwifery in the University of Edinburgh. *Vice-Presidents*: T. S. Combe, M.D., John Taylor, M.D., Samuel A. Pagan, M.D. *Ordinary Councillors*: John Gairdner, M.D., Richard J. Mackenzie, M.D., Benjamin Bell, F.R.C.S.E., James Struthers, M.D., Alexander Ziegler, M.D., James D. Gillespie, M.D., J. Matthews Duncan, M.D., Andrew Wood, M.D. *Treasurer*: Robert Omond, M.D. *Secretaries*: W. T. Gairdner, M.D., 18, Hill Street; J. Warburton Begbie, M.D., 21, Alva Street.

PRACTICAL REMARKS ON THE MINERAL WATERS OF HOMBURG.

BY W. SCOTT, M.D.

Dr. SCOTT referred to the comparative ignorance that prevailed in this country as to the waters of Homburg; and he mentioned that Dr. James Johnston had omitted mention of them in his work on the spas of Germany. He would plead these facts as an excuse for bringing under the notice of the Society a few remarks on a German watering place, in which he had resided for some time.

Dr. Scott gave a brief detail of the situation of Homburg, and noted its rapid increase in population. In 1841, it contained only 1071 inhabitants, while in 1852, they had increased to 6000 or 7000. The chief springs were the Elizabethen-brunnen, the Kaiser-brunnen, the Stahl-brunnen, the Sauer-brunnen, and the Bad brunnen. Their chief ingredients were muriate of soda, muriate of lime, and carbonate of iron; which in their varying proportions constituted the peculiarities of the different springs. Thus the Kaiser-brunnen contained half as much more of muriate of soda than the Elizabethen-brunnen, and double the quantity of muriate of lime; and consequently was a stronger water. Again, the Stahl-brunnen contained double the quantity of carbonate of iron found in the first mentioned spring. The Sauer-brunnen was a milder aperient, and less chalybeate, for a similar reason.

Generally speaking, these springs were employed in chronic affections of the skin, scrofula, and syphilitic diseases. Occasionally, however, they were found to be too irritating in certain cases of skin affection. Again, in scrofula, benefit was obtained from adding the lees of salt, which, from the iodine contained in it, appeared to have a good effect. It was chiefly, however, in conjunction with other springs that most benefit accrued from their use.

The season extended from the middle of May to September;

and during this period, from the sheltered situation, the temperature was remarkably regular. The time for taking the waters was from 6 to 9 A.M. The baths were generally taken three hours after breakfast. In the dietary, which Dr. Scott gave at length, he recommended the avoidance of vegetables, as potatoes and fruits.

Occasionally disastrous effects were found to follow the use of the waters. He referred at length to the case of the late member for Peterborough, whose death had occurred in July last. This gentleman had long been suffering from a disturbed state of the bowels, and a variety of treatment was had recourse to in vain. He tried the waters; but they produced a spasmodic affection of the bowels, which led to a fatal issue. The case too of the late Duke of Nassau might also be mentioned, where death suddenly took place after using the bath. As to the so called *Bad-krisis*, with its disagreeable train of symptoms, he thought it might be entirely obviated by giving some mild alterative, or suspending for a time the use of the waters.

In his own experience, he had found the waters of Homburg especially useful in all forms of biliary derangement, and particularly in the dyspepsia resulting from too close attention to business; although, no doubt, a good deal of the benefit obtained was due to the change of scene and mode of living, etc. Also in rheumatism and gout: in hepatic diseases, although perhaps here Homburg was surpassed by some of the thermal springs of Bohemia; in female complaints, in which, next to dyspepsia, the most benefit was obtained: and finally, in chronic catarrhal diseases, and in glandular and hæmorrhoidal affections. As to the affections of the skin; the various forms of herpes and impetigo were found especially tractable. Generally speaking, the waters were contra-indicated in all acute and febrile diseases, in organic diseases of the heart and lungs, and in cases with tendency to congestion of the head. He cautioned against the use of the waters in cases of irritability of the stomach, where it depended on disease of the kidney. In conclusion, Dr. Scott mentioned that Artesian wells were being bored, which would add greatly to the present supply; and recommended to the notice of the Society the late work of Frederic Müller, on the waters of Homburg. The waters of Homburg contained no bromine, and thus differed from those of Kreuznach.

Professor SYME had found that the use of mineral waters generally aggravated hæmorrhoidal affections. As to the case of sudden death mentioned by Dr. Scott, he attached little importance to its having occurred after taking the bath; as patients at these mineral springs were so continually going in and out of the baths, it was no wonder that death should overtake them in one or other of these processes, just as it did other people in their beds.

Professor SIMPSON, in inquiring of Dr. Scott as to the differences subsisting between our own Scotch mineral waters and those of Homburg, stated that in this country the chief ingredient was muriate of lime. He had latterly seen good reason to adopt Sir Robert Carswell's views with regard to fibrous tumours of the uterus; viz., that they were merely a nodose collection of the ordinary tissue of the uterus, and liable to go backwards, or undergo a species of involution, just as took place in the normal uterus after delivery. If this were the case, the beneficial effects of the waters of Kreuznach were easily explained. Cases, however, he had seen which had returned to this country without the slightest benefit; and in such the sustained use of bromide of potassium was followed by marked diminution in the size of the tumours; in one case, fully one half. This salt is more potent than the iodide of potassium; and seems to be useful as a tonic, as well as a deobstruant. In two cases in his practice it produced salivation. Dr. Locock had stated to him that several of his cases had been much bettered by the Kreuznach waters. But in a case which had occurred lately in Dr. Simpson's practice, no good had followed the use of the waters, though the medical attendant at the place thought otherwise.

CONTAGIOUS NATURE OF CHOLERA. BY DR. TRAILL, OF ARBROATH.

This paper consisted of a succinct and remarkably accurate investigation into the history of all the cases of cholera which had occurred in Arbroath, during the very recent visitation of the epidemic. The cases in all amounted to twenty-six, of which fifteen died, eight recovered, and three were still under treatment. Of the twenty-six, four cases were ascertained to have been imported; in thirteen, no communication with infected individuals could be traced; and in nine, the information was faulty. In five of the cases, cholera was only fully devel-

loped after removal to the House of Refuge; but all the cases were affected with diarrhoea. Of the nurses, one died; but all suffered from diarrhoea. Five of the patients were of dissipated habits; two remarkably so: the remainder consisted of children and of persons reputed sober. In the town itself there is a general want of good dwelling places for the labouring classes. The water, which is obtained from wells, is abundant, and the soil rests on dry gravel. The sanitary condition of the town, which is above par, does not explain the occurrence of the disease.

The statement was tested by reference to a neighbouring locality in the town, in nearly precisely similar circumstances as regards sanitary condition, and containing a hundred and thirty inhabitants. Of these, not one took the disease. And a more striking instance was cited in the case of the row of six cottages, where the disease first made its appearance. In all, the drainage was imperfect; but the cottages to the west were more favourably placed than the others. In the four centre cottages, there were twenty-seven persons. In the two end ones, twelve lived. Of the twenty-seven, all but one escaped, and that was an infant. Whereas, of the twelve inhabiting the end cottages, six took cholera, four choleraic diarrhoea, and two suffered from diarrhoea. Dr. Traill did not undervalue the importance of sanitary reform; but he confessed to being convinced, by his late experience, of the contagious nature of cholera.

Professor SIMPSON called on Dr. Tait, of Dunse, to favour the Society with an account of the recent epidemic in that town.

Dr. TAIT stated, that of the ten cases which had occurred, he had only seen eight. Between the first and second cases, no communication could be traced; but the houses were contiguous. The drainage was bad. Case No. 3, lived about one hundred yards from No. 2; he was a railway-guard, and had communication with Newcastle in the discharge of his duties, he suffered from diarrhoea for a day or so, and was drunk the day previous to his seizure. No. 4 was the wife of No. 3. Nos. 5 and 6, the Knoxes, father and daughter, lived in the middle floor of the same house as Nos. 3 and 4, who were waited on by the daughter, and had some clothes washed by her. One old woman who resided on the same floor with Nos. 5 and 6 had no communication with persons labouring under cholera, and escaped—the same is true of three people who occupied the ground floor. No. 7 lived several hundred yards away from the last cases. He was the sexton, and had, on several occasions, assisted the nurse in waiting on those affected. No. 8 was the late Dr. Drysdale, who attended all the cases; but on the day of his seizure was more than usually exposed, as for three hours he had to officiate as nurse, and from the extreme jactitation of the patients, was brought into closer contact with them. No. 9 was a woman who came to attend upon the Knoxes, and was of drunken habits. No. 10 was the wife of No. 7, she assisted occasionally in nursing, she died of the consecutive fever. Case No. 1 was of a delicate frame of body; while case No. 2 was of intemperate habits. The drainage in the neighbourhood of both their houses was very imperfect. Such facts no doubt gave a strong predisposition. He had remarked the immense number of midges which loaded the atmosphere during the prevalence of the epidemic. In Dunse, the average duration of the disease was from twenty-four to twenty-eight hours. The whole duration of the epidemic was seventeen days, and the number of cases of diarrhoea was twenty.

Dr. LOWE of Saughton Asylum, stated that the midges made their appearance before the cholera; but that when it appeared, they were replaced by the aphides, perfectly distinct from the midges, and widely different in habits.

Dr. W. T. GAIRDNER, during the cholera visitation of 1848, had issued circulars to various surgeons throughout the country, requesting reports of the progress of cholera in the affected districts. At first he was inclined to regard the disease as non-contagious; but before many reports had reached him, the evidence as to its contagious properties became to his mind irresistible. No doubt cholera was less contagious than typhus; but the evidence of its contagious properties was precisely similar.

First:—cholera followed the track of Typhus in any given locality; the same houses were attacked, and in the same order; it might be said, however, that the only similarity was, that in both instances dirty places, under bad sanitary conditions, were attacked. But cholera sometimes attacked places by no means the dirtiest and worst in a locality; and even then, the same houses or streets were the seat of both diseases; proving that their mode of propagation is not very different. This was well

illustrated at Mauchline, where the affected locality was limited in extent, and by no means the worst in the town.

Second:—In a large proportion of cases, an importation of the disease could be made out in towns or villages, if not in the first cases, at least before the disease had become epidemic. Even where, as in the case of Stirling, importation was not made out, there was every reason to believe it might have been discovered, had all the facts been known. In this instance, the epidemic was observed gradually to close in on every side, till within a mile or so of the town, and there was no doubt that the first cases that occurred in Stirling, were precisely at that part of the town which had most communication with the nearest affected village in the neighbourhood.

What had we in these reports that was adverse to the doctrine? From Selkirk we had the vague statement, that the communication with the surrounding districts was very limited; in other cases the disease appeared to arise in isolated localities within the town; but it was difficult to construct a strong argument out of these merely negative facts. In Dumfries, in the epidemic of 1832, the medical men opposed the idea of contagion, and in 1848, there were some of them very strong non-contagionists. The first report that was received from Dumfries declared that the patients in their general hospital had remained quite exempt from cholera, although exposed, without any precautions against infection, to the presence of cholera patients, and stated that the attendants upon the sick had remained likewise free from the disease. These statements did not satisfy the medical man who had treated most of the cases in hospital, and who had therefore the best opportunity of knowing the facts. From his report, and from a correspondence in the *Medical Times*, it appeared, that in 1832 no cholera patients were admitted into the hospital; in 1848, however, cholera cases were admitted, and there were separate wards provided; but notwithstanding the utmost care to avoid infection, of five nurses, one took cholera and died, while many of the patients had attacks of diarrhoea. Of the nine medical men of Dumfries, one died, and more than a half of their number were confined with diarrhoea. Two of the twelve special assistant medical men were attacked, and one died. The report from Falkirk by Dr. Hamilton, that from Kilmarnock by Dr. Hood, and the one from Kilwinning by Dr. Craig, were all strong in their evidence in favour of contagion. The small proportion of victims among the general population in the last-mentioned locality, gave strong evidence of the contagious character of the disorder. The first person attacked was the grave-digger, who had attended thirty cholera funerals before his seizure: the second was his father, living in a separate house: the third was his sister-in-law, also in a separate house, and at some distance: the next were her two children; then two married sisters of the first victim; and lastly, the husband of one of these, and the son of the other. This was only one specimen out of many facts which had reached him, similar to those so clearly narrated by Dr. Traill.

Professor SYME drew attention to the facts connected with the removal of the smack *Trusty* from Leith, to the Hope at Queensferry, where one fatal case had occurred among the officers of quarantine.

Professor SIMPSON said, that on the arrival of the smack at Leith, a boat went out to her with a pilot, and brought two individuals on shore; these were the first cases that occurred in Leith. The vessel was now sent to the Hope. The captain having mentioned his fears that cholera-subjects had formed a part of his cargo from London, his cargo was put on one of the Lazarets; the sick and the healthy were removed to the other Lazaret. Two or three of those on board, and among the sailor-nurses took ill. Round about, there were many ships stationed, and some of their crews were affected. Dr. Simpson could only regard the crew of the *Trusty* as so many tons of contagion. Dr. Simpson of York, had mentioned to him that the very reverse of what had taken place at Stirling, had occurred in that city. The cholera was found to radiate from York into all the surrounding villages, as an imported disease. At Knaresborough, however, the medical man had searched in vain for evidence of its importation, but in a cursory visit which Dr. Simpson of York, had paid to the town, he found that the two first patients had lived at the opposite ends of the town, and no communication could at first be traced between them; but it was ascertained that the two had met at an inn where a traveller had died of cholera, and that they had assisted at the secret removal of the body.

Dr. BEGIE had never been impressed with the idea that the ordinary mode of propagation of cholera was by contagion; and the cases in Arbroath related by Dr. Traill, in no measure altered that opinion. No doubt the importation of the first and

second cases from Dundee, where the disease was prevalent, and the occurrence of the third and some of the subsequent cases after communication with the two first, was calculated to lead to the impression that the spread of the disease was by such communication; but when we considered that out of twenty-six cases, comprehending the whole of the epidemic, there were no fewer than nine who had no communication with those first affected, or, so far as he understood, with each other, the evidence failed to satisfy his mind that there was anything more than a coincidence between the occurrence of the disease in Abroath, and the return of the first and second cases from Dundee. Its subsequent spread appeared to him to be from epidemic influence, connected with atmospheric and telluric causes at that time set in operation in the former place, and not to importation. He had long been satisfied that cholera was not contagious in the ordinary acceptance of the term, from his own experience during the first epidemic of the disease in this city in 1832. On that occasion, he had been appointed along with Dr. Hamilton Bell, to the charge of the first hospital for the reception of cholera-patients, and during the six months he had officiated there, no instance occurred of the disease having been communicated to any of the medical men in attendance, or to any one of the establishment of servants, nurses, porters, or to any visitor, of whom there were many. During the whole course of the epidemic in Edinburgh, only one practitioner died of the disease; and he had not attended any cholera-patient, having from the first entertained a great dread and apprehension of its effects on his own person. The occurrence of the disease in Dumfries had been referred to. The invasion of the disease there, was a strong proof of its non-contagious nature; for how could the well known circumstance of forty or fifty cases occurring at the same time, in the course of one night, on the first out-burst of the disease there, be accounted for by importation; or the sudden termination of the epidemic without spreading to other immediately contiguous places?

Dr. MYRTLE gave the result of his experience in the City Quarantine House during the epidemic of 1848, where only two or three cases occurred among many hundred persons drafted from the most wretched quarters of the town, many of them suffering from diarrhoea.

Professor BENNETT thought, from the tenor of the discussion, that the Society was coming to the conclusion, that if cholera was not contagious in masses, it might be so in detail. Now, if a small village were attacked, there appeared to be little difficulty in obtaining evidences of contagion. But in a large town, such as London, the doctrine was not believed in: and the same was the case with regard to India. The strongest argument against the contagious nature of cholera, was the fact that the disease progresses from east to west. Now what is contagion? It is usually regarded as the propagation of disease by touch or contact; while infection includes propagation by means of particles in the air. If the cholera progresses from east to west, it can be by neither of these two ways. Russia has again and again, with its armies of quarantine, attempted to check its advance; and yet the disease has progressed in its usual direction. This has been done three times, and the same result has followed. It never progressed in directions running north and south, or west and east. Cholera cannot therefore be contagious. If studied where it attacks masses, it cannot be proved to progress by contagion; but it is from little villages, where all the inhabitants are known to each other, and where the field of observation is very contracted, that the only arguments of the contagionists are drawn.

Dr. SCOTT agreed with the remarks of Dr. Bennett, and instanced the case of a ship in Bombay Harbour suddenly struck by a land-squall, and in which, in a few hours, eighteen died of a crew of a hundred and forty: on the removal of the infected crew to an island, the disease had as suddenly disappeared.

Professor SIMPSON, in answer to Dr. Bennett, begged to remind him that, as far as mere progress was concerned, the contagious exanthemata, small-pox and measles, had, in their first arrivals from the east, the same history as cholera. Again, cases of cholera had occurred in ships crossing to America; but there was no instance on record of one occurring on the voyage from America to Britain. Again, in no ship starting from England for India, and of course not touching at any infected port by the way, has the cholera ever broken out; although, on Dr. Bennett's showing, it ought to have done so.

Dr. W. T. GAIRDNER objected to the statements of Dr. Bennett, as to the progress of cholera in the mass. If cholera was contagious in detail, then he thought that evidence ten times as strong existed to its contagion in the mass. From India the cholera radiated in all directions; and the law of its progression

was apparently that of human intercourse. It passed from India indifferently to Siam, China, Ceylon, the Punjab, and to Persia. From the latter it proceeded further; and why? because this was one of the great lines of human intercourse. It was conveyed to the island of Bourbon by a ship; and, wherever it crossed the ocean, it followed the track of ships, and landed at sea-port towns, which were always the foci from which islands and isolated countries and continents became infected. If this did not constitute a strong probability that cholera was contagious in the mass, he did not know what could do so.

Dr. ALEXANDER WOOD granted that cholera was not propagated by contagion only; but he was greatly surprised to hear of no contagion. The statements in the paper of Dr. Traill, and the admirable remarks of Dr. Gairdner, contained to his mind irresistible evidence to show that cholera is contagious. It was very strange that Dr. Bennett should try to set this evidence aside. India was the great focus of the disease, and, as every one knew, lay to the eastward of Europe; and of course any disease starting from India, naturally reached us from the east. There was no doubt that cholera was more contagious here than in India. An Indian officer had lately informed him that a body of troops lay encamped, with a river running through the encampment, and separating the infantry from the cavalry. The cavalry hospital was on the same side as the infantry: the disease raged among the cavalry, while the troops on the opposite bank escaped. But the cavalry sentinels stationed round the hospital were seized with the disease; and in the previously healthy villages, where the clothes of the soldiers were sent to be washed, nearly all the inhabitants were seized. How could this be explained, except on the admission that cholera is contagious? The American reports bear similar evidence. Why is contagion so easily proved in villages? Because the communication with the sick can be more easily traced. With regard to cholera, we must come to the same conclusion as we do with regard to other diseases, such as small-pox, etc., etc.: that, though not necessarily contagious, yet they may be so. Dr. Begbie had stated that no attendant, etc., had been attacked in the Cholera Hospital on the Castle Hill during the first six months of the epidemic of 1832; yet cases occurred to show its contagious nature, and the disease spread from the hospital. In Surgeons' Square Hospital, the cholera attacked the nurses, in the proportion of one in five. A short visit of a medical man to a well appointed hospital proved nothing; but friends calling upon the sick in ill-ventilated and small apartments, gave a different result. He was clearly of opinion that, in the Abroath epidemic, the existence of any telluric influence was to a great extent disproved.

LIVERPOOL MEDICAL AND PATHOLOGICAL SOCIETY.

THURSDAY, OCTOBER 20TH, 1853.

JOHN CAMERON, M.D., in the Chair.

DROPSY OF THE UPPER HALF OF THE BODY, FROM A TUMOUR ENCIRCLING AND COMPLETELY CLOSING THE SUPERIOR VENA CAVA. BY JAMES TURNBULL, M.D.

On the 3rd of Sept. 1853, Mr. Blower requested Dr. Turnbull to see in consultation a remarkable case of dropsy of the upper half of the body, which had been under his care for about ten weeks, and had also been seen by various other medical men. The gentleman was twenty-six years of age, of fair complexion, and did not appear of unhealthy constitution. His breath had become rather short about the end of May; and when he first consulted Mr. Blower, it was on account of dyspeptic symptoms and headache. Soon afterwards, however, he had several attacks of severe spasmodic pain at the stomach, which were relieved by the use of hot applications. It was observed that on stooping his face became swollen and livid. The patient also found that he could not button his shirt collar. It was then discovered that the neck and chest were oedematous, and the veins of the chest enlarged and tortuous. All these symptoms had much increased when Dr. Turnbull saw the patient; the difficulty of breathing was so great, that he could not lie down; the face was much swollen; the lips somewhat livid; and the neck, the front of the chest, and the arms, pitted on pressure. There was a distinct line about the margin of the ribs, separating the oedematous from the non-oedematous part. Over the whole front of the chest there was a tortuous network of enlarged veins of deep blue colour, which emptied themselves into the two epigastric veins, which were also much enlarged. Two enlarged veins were also seen along the back

of the chest, where, however, there was scarcely any perceptible œdema.

Physical Signs. Over the centre of the sternum there was very decided dullness on percussion; and there was also more than the ordinary amount of dullness in the region of the heart. This dullness was partly attributed to the œdematous state of the parts. There was dullness over the whole of the lower parts of the left side of the chest; and behind the dullness reached as high as the centre of the scapula. There was also absence of respiration inferiorly, and other signs of effusion. At this period, there were no signs of any considerable effusion on the right side; but a subsequent examination showed that fluid had accumulated here also. The sounds of the heart were natural, but dull and distant; and no impulse could be felt. In the course of the aorta, no pulsation or murmur could be perceived.

Diagnosis. The condition of the veins and the œdema of the upper parts of the body, showed clearly that there was obstruction to the return of the venous blood through the superior vena cava; but the cause of this obstruction was less obvious. The following were considered to be the possible causes:—1. Closure of the veins from the effects of inflammation of the coats. 2. The pressure of an aneurism. 3. Pressure of a cancerous tumour of the lung upon the vein. 4. Pressure of a tuberculous gland upon the vein. There was nothing in the history of the case to lead the obstruction to be attributed to any one of these causes more than to another. There had never been any pain, except when the patient had the temporary spasmodic attacks; and there was no special reason for thinking that it had arisen from inflammation of the vein itself, which would have been the least injurious of the causes of obstruction, seeing that the circulation might have ultimately accommodated itself to it. Aneurism was considered to be one of the most common causes of pressure upon the vena cava; but the course of the aorta had been carefully examined, without any murmur or pulsation being detected. There were no well marked symptoms of pulmonary disease; and the age and appearance did not seem to indicate the probable existence of cancerous disease of the lung or other parts. It did, however, appear not improbable, especially as there was so much dullness over the sternum, that there might be tubercular enlargement of the bronchial glands.

The treatment was directed with the view of promoting absorption of any glandular enlargement or effusion of lymph or serum resulting from inflammatory action. He had, before being seen by Dr. Turnbull, been treated with hydragogue cathartics; the left side had been blistered; and his mouth was slightly affected with calomel. A diuretic pill, containing squill, digitalis, and blue pill, was given twice a day, with the view of maintaining the mercurial action for a short time; and a mixture, containing iodide of potassium and liquor potassæ, was prescribed. These and other means failed in producing any impression on the disease; the quantity of fluid in the left side of the chest increased, and it accumulated in the right side also, producing most urgent dyspnoea. He also complained of a feeling of fulness and pressure at the stomach. On the 25th of September, he died.

EXAMINATION OF THE BODY. On endeavouring to raise the sternum, it was found to be adhering at every part to a large tumour, which occupied the whole of the anterior and extended into the posterior mediastinum. It spread on each side beyond the cartilages of the ribs, covering and adhering to the corresponding portions of both lungs. A very dense portion of the tumour covered the heart; and the tumour and pericardium were inseparably united. It had grown along the large vessels, and the superior vena cava was completely encircled and obliterated by the pressure of a portion of the tumour. A soft fibrinous looking clot appeared to have completed the closure of the vessel. The vena azygos, which entered the cava above the obstruction, was much enlarged. The tumour rested inferiorly upon the diaphragm, and laterally and posteriorly, in which directions it was extending itself, it had a nodulated appearance. It was firm in structure, and could not be broken down with the fingers. Internally it had a variegated aspect, like some kinds of marble, the greater part being of a grayish white colour, with nodules of a more yellow colour. Under the microscope, numerous nucleated cells were visible, but none of the tailed cells so common in most cancerous structures. There could not, however, be any doubt that the tumour was of malignant nature, and growing rapidly.

REMARKS. The most prominent symptoms in this singular case were the varicose enlargement of the veins of the chest, and the dropsy of the upper half of the body, to which part it

was confined until the circulation became generally obstructed by the effusion into the chest and the great dyspnoea. The late Dr. James Carson, jun., brought before this society several years ago two cases of a similar kind, and Dr. Turnbull had the opportunity of repeatedly seeing one of them in the Northern Hospital. The patient had the same varicose enlargement of the veins and œdema of the chest and face as was observed in this case, but he recovered, and was afterwards able to pursue a laborious occupation. The enlargement of the veins, however, continued; showing that the obstruction to the venous circulation must have been permanent. In the other case, the obstruction was produced by pressure from a scirrhus tumour of the lung resting upon the superior cava. Dr. Watson related a case similar to the one now detailed, where the obstruction arose from a large aneurism of the arteria innominata pressing upon the vena cava, at the point where the two great trunks unite to form the cava. Dr. Peacock, in a paper in the *Medico-Chirurgical Transactions*, states that complete obstruction of this vessel is extremely rare, having been so in only three out of nine cases he had been able to collect.

With respect to the nature of the tumour in this instance, it would seem, from its firm structure and nodulated appearance, to have been cancerous, and the abundance of nucleated cells would likewise appear to indicate rapid growth. It may be more difficult to decide in what structure it originated. Its complete incorporation with the pericardium, and the way in which it had extended along the vessels, might seem to show that it had originated in this serous membrane; but it had also extended in a similar way along the pleura pulmonalis and costalis. It was in close contact with the whole of the posterior surface of the sternum, occupying the situation of the thymus gland, no trace of which was observable. It is therefore probable that it may have begun in this body; and Dr. Walshe states that, though no case of cancer of the thymus gland had come under his notice, there could be no reason to doubt that carcinomatous disease of this organ does occur.

ASSOCIATION INTELLIGENCE.

METROPOLITAN COUNTIES BRANCH:—SPECIAL GENERAL MEETING.

A special general meeting of the Metropolitan Counties Branch was held on Tuesday, 13th December, at 37, Soho Square. The President, Sir JOHN FORBES, M.D., occupied the chair. The following members were present:—Henry Ancell, Esq. (London); John Bowling, Esq. (Hammersmith); John Rose Cormack, M.D. (Putney); R. P. Cotton, M.D. (London); Benjamin Davies, M.D. (London); Alexander Henry, M.D. (London); C. F. J. Lord, Esq. (Hampstead); John Propert, Esq. (London); B. W. Richardson, Esq. (Mortlake); R. H. Semple, M.D. (London); Edward Waddington, Esq. (London); George Webster, M.D. (Dulwich); Robert Willis, M.D. (Barnes), etc.

The PRESIDENT said, that the meeting had been convened by the Council for two objects; FIRST—To consider what steps ought to be taken with reference to the Vaccination Act; and SECONDLY, to receive and consider the Report of the Medical Reform Committee. In the absence of Dr. Webster, who was to have introduced the first subject, he would suggest that Dr. Semple, chairman of the Medical Reform Committee, should favour the meeting with their Report.

MEDICAL REFORM.

Dr. SEMPLE said, that there was not much of a Report, inasmuch as there had been nothing to do; the Medical Reform Bill not having gone into the House of Commons. The Medical Reform Committee had held one meeting, in accordance with the instructions received from the General Meeting, at which were present a great many veteran reformers. Upon that occasion, the resolutions passed were of a general character, which did not pledge the meeting to support the Bill, and at the same time did not object to it. Dr. Semple then read the following Resolutions adopted at the Meeting of the Committee:

“That this Committee think that it is the duty of the Metropolitan Counties Branch of the Provincial Medical and Surgical Association, to support a Medical Reform Bill, so far as it shall give effect to the great principles of uniformity of edu-

cation, reciprocity of privilege, and the registration of legally qualified practitioners; but that they forbear to express an opinion on the details until an amended Bill is before the Committee.

"That Mr. Hastings, the Secretary of the Medical Reform Committee of the Parent Association, be requested to furnish this Committee with a copy of the amended Bill, as soon as it is possible for him to do so."

They had therefore waited until the amended Bill was laid before them; but although they had waited from that time to the present, namely, from the 27th of May to the present day, they had not yet seen the amended Bill, nor were they aware whether it was in existence. Mr. Hastings, the Secretary of the Reform Committee of the Association, had been requested to attend to-day to give such information as he could furnish.

Dr. OGIER WARD read the Resolution passed by the Council, upon which the meeting was called; also another Resolution passed at the same Council Meeting, to the effect that the Honorary Secretary be requested to write to Sir Charles Hastings, asking him to furnish a copy of the amended Bill. He also read parts of a letter from Sir Charles Hastings, the substance of which was, that he had no objection to the proof of the Bill being seen by him (Dr. Ward), but that it was impossible for it to be made the subject of criticism, as it had not yet received the sanction of the Reform Committee, who had not yet met to consider it. For the convenience of the members of that Committee, who were to meet at Birmingham on the 19th instant, the Secretary's draft had been put in type; but it was at present a strictly private document, and must so remain until the Committee authorized its publication. Sir Charles mentioned that the College of Physicians of London was favourable to the Bill of the Association, and that on all hands there were encouraging signs. He concluded his letter by stating the great necessity of conciliation and mutual concession in settling the great question of medical reform.

Mr. PROPERT thought a great deal of time would be saved, if Mr. Bowling would at once communicate what had transpired between Lord Palmerston and himself within the last few days.

Mr. ANCELL wished to know the object of the present meeting. He understood there was to be a meeting at Birmingham on the 19th, on the subject of a new Medical Reform Bill, or rather an amended Bill. If he had not misapprehended the matter, the object of the present meeting was to consider the propriety of making a communication to the Reform Committee previous to the meeting at Birmingham.

The PRESIDENT thought that, as far as the official announcement went, the objects of the meeting were quite general. The reception and consideration of the Report of the Medical Reform Committee, he presumed, might give rise to propositions to be communicated to the meeting at Birmingham, or anything else connected with the subject.

Mr. ANCELL hoped that the members present would well consider, whether the Bill about to be placed before the Association was a Bill which would give satisfaction in essential particulars. He was prepared to give way in all minor points, but he could not say, following the letter as carefully as he was able, that it appeared to embrace what he deemed to be essential points; for instance, it did not embrace the question of representation or the constitution of the Council, upon which subject the greatest difference of opinion existed when the former Bill was under discussion. He (Mr. Ansell) thought it was most desirable that a Bill should be produced which all parties could agree in, and cordially support, in order to secure its passage through Parliament.

Mr. BOWLING, having been personally referred to, would state what occurred at an interview which he had with Lord Palmerston on Wednesday the 7th inst. He saw his lordship upon the sanitary condition of Hammersmith. After they had completed that business, Mr. Bowling said, "My lord, will you have the kindness to tell me if there is any probability of a Medical Reform Bill being brought into Parliament early next session?" His lordship said, "I will tell you. I have found so much difficulty in the question, that I have contemplated the appointment of a commission to inquire into the whole subject." Mr. Bowling replied, "I am very glad to hear it, my lord, because you must be aware that we are in a very distracted, and uncomfortable state." Lord Palmerston said, "I am quite aware of it." He meant to have asked his lordship if he had any objection to his mentioning to-day, what had passed between them; but when he recollected that there were several other gentlemen present, he did not think any secrecy attached to the conversation. He thought the meeting ought to consider whether it should appoint a deputation, either to wait upon Lord Palmerston, or

to write to him, to ascertain as far as possible, under what conditions he would propose the commission, and who were likely to constitute that commission; and then it would be seen how far it was a commission likely to meet the present state of affairs.

Dr. WEBSTER would state, in reference to what Mr. Bowling had said, that he had had the honour of an interview with Lord Palmerston on the same day; and imbued with the same inquisitive spirit, he also stopped behind, and had some conversation with his lordship. Something very similar passed, as between Lord Palmerston and Mr. Bowling. He (Dr. Webster) said, "I had once the honour of an interview with your lordship on the subject of Medical Reform, might I ask whether there is anything likely to be done, whether the time is approaching, and steps are being taken? I have received an invitation to go down to Birmingham upon this subject, being a member of the Reform Committee." His lordship said, "You are not agreed. The great difficulty has been, that the profession is so disagreed upon the subject." Dr. Webster said, "My lord, I think that seems a reason that is not quite so tenable as it at first sight would appear to be. How can you expect that highwaymen, and those who are robbed should agree with each other?" He did not apply the term in any offensive sense. "We are complaining, and have for years and years been making complaints, of the monopolizing spirit which the Colleges have displayed. How can you expect that we, the aggrieved parties, should in everything bring our ideas to square with those, who have shown themselves, in many respects, unworthy of the powers which they hold? I think really that unless you, my lord, with a strong government take this matter up, and bring forward such a measure as to the government shall seem just, there will be no end to the question. Your lordship will put us off to the Greek Kalends, if you wait till we are agreed." He said, "I did think of appointing a Royal Commission." Dr. Webster did not encourage the idea, because he knew too well the materials of which Royal Commissions are generally composed. He did not like to ask his lordship to go into the materials; he thought that the appointment of a Commission would merely delay the question a great deal longer. All the physicians and surgeons of the different Colleges would be called to give evidence, and the same thing would happen, that has happened before. There have been two or three Parliamentary inquiries, and they have not tended to bring the profession into unity. Dr. Webster also had received a letter from Sir Charles Hastings, in which he said that he did not think the Bill to be in a state to be made the subject of discussion, not yet having passed the ordeal of the Reform Committee. At the end of the letter, Sir C. Hastings had written: "I have received a letter from Dr. Ogier Ward, the Secretary of the Metropolitan Counties Branch, forwarding a resolution requesting a copy of the amended Bill, to bring before the Branch on Tuesday next. Under the circumstances, I do not feel it right to withhold the Bill; but I have written to Dr. Ward, explaining to him that the bill has not received the sanction of the Committee: it was only put into type for convenience.... You will of course receive a proof copy of the bill. I hope you will be able to attend the Branch meeting on Tuesday. You will then explain that the amended Bill cannot well be made the subject of public discussion until it has been formally adopted. I hope you will be able to attend the meeting at Birmingham on the 19th, as it will be very desirable to fix on our plan of proceeding. I can only hope that a conciliatory spirit may prevail relative to those points on which opinions differ; for our opponents will endeavour to persuade Lord Palmerston that we are a divided set, and may drive him from medical legislation next session. I have within these two days had a gratifying proof of great unanimity by the receipt, through their Secretary, of £5 from the Medical and Surgical Association of Gloucestershire, in aid of the funds. I am sorry I cannot attend the Branch meeting." As a member of the Medical Reform Committee of the Parent Association, Dr. Webster would not think it right to say much upon the subject; but, being also a member of this Branch, he thought himself at liberty to express his opinions upon it. His great objection to the last edition of the Bill was the same as that of Mr. Ansell, namely, to the constitution of the superintending or governing Council. One of the principles for which this Association had always contended was a fair representation of the profession in the governing bodies. He could not say that he thought that there had been introduced into the Bill a fair representation. Unless there were a thorough representation of the whole of the profession, instead of sections of the profession, in the Col-

leges, he thought it would be quite unsafe to allow the government to appoint the members of the superintending Council, irrespective of the medical profession. The way in which it was now proposed was especially unjust to the great body of general practitioners; because the corporations would be fully represented, whilst the great mass of the practising surgeons would be unrepresented.

Mr. RICHARDSON (of Mortlake) thought it was very necessary that the Metropolitan Branch should express its opinion to the Reform Committee on the subject of the Reform Bill. He gathered from what took place at a previous meeting, that all who knew anything about the Bill complained that it did not take in the representative principle. Dr. Webster was formerly a little more inclined to compromise than he appeared to be at the present moment. He (Mr. Richardson) thought that the members of the Association would agree with him, that it was fortunate Lord Aberdeen had not allowed the bill to pass last year. Throughout the land, the power and the absolute fairness of the representative principle was fully recognised; and all the members of the Association with whom he (Mr. Richardson) was acquainted, were full of hope that this great principle would soon be introduced into the Association itself. Feeling the importance of keeping in view the necessity of representative Councils, he begged to lay before the meeting the following resolution:—

"That, in the opinion of this meeting, the Medical Reform Bill, to be introduced into Parliament by the Association, ought to be framed on the basis of the representative principle; and that no Bill can give general satisfaction to the profession which shall lead to the constitution of a superintending Council containing a preponderating influence of the Colleges of Physicians and Surgeons."

Mr. ANCELL seconded the resolution.

Dr. WEBSTER explained, that his reason for viewing the Bill less favourably than at a former meeting was, that concessions had been made since that time of which he did not approve.

Mr. BOWLING thought it was impossible to dissent from the motion, inasmuch as it embodied the representative principle, upon which the Reform Committee of the Association was first established, and was bound to proceed. Upon many points, there were different views amongst the members of the profession; but, upon the subject of representation, there never could be two opinions. A preponderating influence of the Colleges in a governing Council would be highly prejudicial to the general practitioners. So long as the Colleges had the power of making rules, and, to a certain extent, establishing the curriculum, so long must the general practitioners find that they were under the debasing influences which they had always experienced. The Colleges declared that it was necessary there should be an inferior grade of practitioners. This had been avowed to the members of successive governments, and it must be submitted to as far as emoluments were concerned. The meeting would not do its duty, if it did not insist upon the representative principle being carried out to the utmost extent.

The PRESIDENT inquired of Mr. Richardson, whether he meant by his motion that the governing body should be constituted on the representative principle.

Mr. RICHARDSON replied, his meaning was that every man in the profession should have a vote in the election of the Council.

Dr. CORMACK observed, that it would be better for the meeting to leave the mode of carrying out the representative principle a little indefinite. The Reform Committee would probably have various suggestions to consider regarding this part of the measure. The best of all representative Councils would be a Council elected by the Colleges, *provided the profession were fairly represented in the Colleges*. If once representation of the profession within the Colleges could be gained, he believed all difficulties would be disposed of.

Dr. WEBSTER had great doubts whether it would be possible to give every member of the profession a vote in the election of the Council; and he agreed with Dr. Cormack, that the more indefinite and general the terms of the resolution were, the better. It was not expedient at present to go into details.

The PRESIDENT asked if the resolution could not be worded, "that no Bill was to be sanctioned which did not recognise the representative principle in the governing bodies."

Mr. RICHARDSON: That is again confining all the power to the governing bodies.

The PRESIDENT supposed that the representative principle would imply, that the governing bodies were to be elected according to some system of representation, though it might not

go to the extent of voting by every individual member of the profession.

Dr. CORMACK suggested the addition of the words, "as at present constituted", to the end of the motion.

Dr. WEBSTER thought that great force would be given to the motion, if the words "the Colleges" were introduced in the body of the resolution before the words "Superintending Council", because great changes would most likely be made in the Colleges by any Bill.

The resolution in the following amended form was carried unanimously:—

"That in the opinion of this Branch, the Medical Reform Bill to be introduced into Parliament by the Association should recognise the necessity of the representative principle, generally extended, in the election of the governing bodies of the Colleges and of the Superintending Council; and that no Bill can give general satisfaction to the profession which shall tend to the constitution of a Superintending Council, containing a preponderating influence of the Colleges of Physicians and Surgeons, as at present constituted."

Mr. LORD said, that in proportion as the elective franchise was extended, it became necessary to look closely at the capabilities and acquirements of the men who were to exercise that franchise. It struck him as being an extraordinary provision, that twenty-one years of age should be the minimum at which a man should be considered capable of entering the profession. He thought a more extended period necessary, in order that a greater portion of early life should be devoted to the laying a solid foundation of knowledge, on which might be reared the capacity of properly exercising the elective franchise for the good of the profession at large; he therefore begged to propose—

"That in the opinion of this meeting, it is expedient that the provision of the former Bill, promulgated by the Reform Committee, which determined the minimum of age at which candidates were rendered admissible into the profession, be altered from 21 to 22 years, in order to allow of a higher standard of qualification in general education, including classics and mathematics, for the profession at large."

Dr. SEMPLE, in seconding the resolution, said that although this was one of the details of the proposed measure, rather than one of its principal parts, he thought it of sufficient importance to demand special attention. Young men were too soon thrown upon the practice of medicine, in this country. The old regulation of the College of Surgeons, that a man must be twenty-two before he had his diploma, was very judicious; because he was enabled to get through his studies, and then, for a year afterwards, to cultivate still more at length the higher branches of the profession, either in the schools of this country or those of the continent: whereas now, a young man of twenty-one, having passed the College of Surgeons upon the basis of a small knowledge of anatomy and still less of surgery, was thrust into the profession. He (Dr. Semple) thought that a year more was of essential importance.

Mr. ANCELL wished to state that this was one of the points on which there was never any difference of opinion in the National Association of medical men, which consisted of four thousand members. That unanimity in favour of twenty-two years instead of twenty-one, was not only on the grounds mentioned by Dr. Semple, but also on the ground that a professional man ought to have secured to him the education of a gentleman and not of a tradesman. Everybody knew that the period from sixteen to seventeen years of age was worth three or four antecedent years. The College of Surgeons made a distinction between members and fellows, but they dropped the age for membership from twenty-two to twenty-one years. He had no desire to impute motives to any one, but the effect of the reduction was palpable, namely, to secure a lower grade of practitioners. The subject was argued by a deputation from the Council of the National Association, and a deputation from the National Institute, with the College of Surgeons, but no reply was ever given as to why the twenty-two years were reduced to twenty-one. Upon that occasion, the great advantages were pointed out, to which no valid objection could be given. A sort of tacit assent had been obtained that the twenty-one would be converted to twenty-two, but now it appeared, if all he (Mr. Ansell) heard was correct, that the Bill was to be proposed with twenty-one years. It was a point of great importance, though it was a matter of detail, which would not affect the principle of the Bill.

The resolution was carried unanimously.

Dr. SEMPLE desired to make a proposition upon the subject of preliminary examination, which he believed to be quite as important as the resolution which had just been passed. He be-

lieved that in all departments of our different public Services—in the East India Company's Service—in the army—in the navy—in the customs, and in a great many other branches, it has become absolutely necessary that those who enter should possess some knowledge of classics and mathematics, of sound English and the rudiments of French—in other words, that they should have a general scholastic education. It was an exceptional fact that our profession was, he thought, the only one in which persons are allowed to practise without possessing any general education. Lamentable ignorance is the necessary result, and great scandal to our profession follows from this inattention on the part of our examining bodies. He was not stating more than the fact, when he said that many persons are sent out as medical graduates from some of our Universities, who are not able to write English; and when those persons pass into the public departments of the army or the navy, the official reports they send forth are a scandal to the profession to which they belong. He was not wishing to make any vituperative remarks. He knew a great deal more than he liked to say, and he would not cast reflections upon individuals or upon public bodies; but this he must say, that it ought to be the desire of every one who wishes well for his profession, that at least the elements of general knowledge should be possessed by medical practitioners, not after they have finished their career at the medical schools, but before they begin it. It was perfectly easy to impose such a test. There was such a test at the universities of Oxford, Cambridge, and London; and other bodies are trying to institute a similar trial. Without specifying any of the bodies which do not require such a test, he would state that there are a vast number of practitioners all over the country who are not required to give any evidence of general education whatever. They pass at once through superficial studies in anatomy, surgery, and collateral branches, and at the end of their term they are ignorant not merely of the elements of Latin, French, and other languages, but, (he said advisedly), they are not able to write correctly their own language. Can we expect our profession to be honoured when such ignorance is not only tolerated, but encouraged? This Branch must give an emphatic expression of opinion, that general preliminary education ought to be insisted upon. He was not requiring that a medical student should be profoundly learned in Latin or Greek or Mathematics; but he did say, that considering the great improvements which have taken place in the conduct of public schools and private schools, and the great mass of information of all kinds which is now diffused throughout the land, and which can be obtained at a cheap rate; if we desire to maintain our character as gentlemen; if we desire to hold rank with the legal profession and the profession of divinity, we must attend to the preliminary qualifications of those who are about to enter our profession. If it is found necessary for a man who is to fight the battles of his country to know something of classics and mathematics; if a man who is about to enter the army or the navy must know something of those branches of education or be rejected from the service; it is still more imperatively necessary in the case of our profession, which is essentially a learned profession, the technicalities of which cannot be understood without the knowledge of reasoning, which is the result of mathematical and logical training. Dr. Semple then proposed the following resolution:—

"That in the opinion of this Branch, the proposed Medical Reform Bill ought to contain a clause, rendering imperative a preliminary examination in classics, mathematics, and general science, before the student commences his medical education."

Dr. WARD seconded the resolution. Instances of the want of the preliminary education spoken of by Dr. Semple had frequently come under his notice; he regarded general education as extremely necessary, not only in the formation of a practical medical man, but in what was perhaps more important—a gentleman.

Mr. ANCELL briefly supported the resolution.

Dr. CORMACK thought that something of the kind pointed at by the resolution, was absolutely requisite. The Pharmaceutical Society was exacting an increased amount of education, and was about to go to Parliament for additional powers. As there was an upward tendency in other bodies, it was high time that the medical profession, when they came before Parliament next session, should take measures to secure and improve their position. There was no doubt the College of Surgeons, by keeping low its standard of education, and the Pharmaceutical Society by raising its standard, tended to cause a return to the state of things which existed in 1815—when there existed upon the one

hand, men profoundly acquainted with their profession, and on the other, at an immense interval below them, a herd of ignorant apothecaries. He thought the public was deeply concerned in the matter: it was a public rather than a professional question, and it was peculiarly the duty of a government to take every means to prevent a relapse to the former state of things, when the services of competent practitioners were only within the reach of the rich. At present a very different state of things prevailed, and the public ought to be shown that it was their interest to secure its continuance, and to prevent the present generation of accomplished practitioners being superseded by mere pharmacists, or by any inferior grade.

Dr. WEBSTER felt quite sure that the authors of the proposed Bill fully intended that a preliminary examination should be passed by all who entered the profession. At the same time, he was of opinion that a declaration of this kind would be useful. The good sense of the profession at large, and of different isolated bodies, was accomplishing that which was now mooted. In illustration, he (Dr. Webster) instanced the voluntary examination at St. Thomas's Hospital, and the examination by the Society of Apothecaries.

The PRESIDENT could not allow the resolution to be put to the meeting, without in a few words expressing his own opinion. He had always felt that the vitality of reform in the profession depended upon making it as much a profession of gentlemen as possible. The influence of classical studies, of the knowledge of science and literature in expanding the mind was perfectly well known. He thought if the year of admission could be raised to twenty-two, and a clause were obtained in the new Act, to oblige a student to be examined before he entered upon the study of medicine, a most important part of the required reform would be gained; because, if the profession consisted of gentlemen with a true sense of dignity in their own persons, there would not be much difficulty in the mere exterior parts of reform; and the members of the profession, from their personal influence, would command the things which they were now soliciting. Whether the examination should necessarily take place before a youth commenced his medical studies, or during the first year might be a matter of detail.

The resolution was carried unanimously.

It was moved by Mr. ANCELL, seconded by Dr. HENRY, and carried unanimously:—

"That a copy of the foregoing resolutions be forwarded by the Secretary to the Reform Committee of the Parent Association, with a request to give to them their most serious consideration."

It was unanimously resolved, that the Reform Committee of the Branch should be requested to continue its vigilance.

THE VACCINATION ACT.

Dr. WEBSTER felt that, if the strict principle of representation had been carried out as regards our own Association, and we had kept a watch at the proper period, the Vaccination Act, which he regarded as injurious to our profession in its present form, would never have been allowed to pass. If our body had been on the alert, and watchful, this question need not have been mooted here to-day. He would not enter into all the details of an Act, which he supposed every gentleman present knew quite as well as he did. He thought the gist of the objections to the Act might be stated in three propositions. First, there are onerous and troublesome duties exacted by the Act, which are not at all remunerative. He need not state the old adage, that "the labourer is worthy of his hire". We do not find other professions anxious to work a great deal for nothing. It has been argued that vaccination was a mere bagatelle, a matter so commonly done for nothing, that we ought not to object to the additional duties which have been laid upon us by this Act. He took quite a different view. He thought that a man has a perfect right, consistently with the rights of the profession, to act gratuitously when he thinks proper. He looked upon this service then as an act of benevolence; but when it is compulsory, it is no longer benevolence. He was not to be told by his neighbour how and to what amount he was to administer his benevolence. It was altogether unconstitutional and contrary to the rights of the subject, to exact that which is exacted by this Act; that is, that we shall perform certain services without compensation for time or skill. The Act obliges us to give repeated certificates, first, to the patient; secondly, to the registrar; and thirdly, from time to time, if we do not think the patient is in a fit state to be vaccinated. In carrying out a measure for the public benefit, care ought to have been taken that private rights were not invaded. The private and just rights of the profession had

been greatly invaded by this measure. We have been fighting a battle with the Insurance Companies; and by perseverance, and firmness, we have brought at least half the London Insurance Offices to pay fees, which were not paid before, to professional men; and if a proper stand were made in the present instance, we should also do good. Many people say that the medical profession is a benevolent profession. It ought to be so; and God forbid that the time should ever come when it shall cease to be so. He was quite sure that many of us have an amount of benevolence forced upon us from circumstances; but he did contend, that we ought not to have onerous duties cast upon us by the legislature. With respect to giving a certificate of the cause of death, it is for the sake of science, and is a great public benefit. Really our good nature ought not to be carried further; and he thought that the time was come when a stand ought to be made. The second point is the miserably low remuneration for the services that are paid for. The minimum of eighteen-pence, which is the general amount of fee paid, looking at the duties which will be exacted from those who contract for Unions, is really a sum which is discreditable to the country to give, and almost so to professional men to receive. Eighteen-pence is the sum which is put down even for paupers. The public very quickly lay hold of these matters; and there is nothing whatever to prevent a person in good circumstances going to contractors. Dr. Webster believed that now a great many do go. Many of his patients had their children vaccinated at the different stations in London, without giving any sort of remuneration whatever. People in really excellent condition in life attend the gratuitous stations, such as Rowland Hill's Chapel, in the south part of the metropolis. He considered eighteen-pence a miserable recompense for the duty to be performed. It was really not estimating either the benefit conferred, or the time and science of the medical man. He thought it altogether inadequate to the occasion. The third point was, that the working effect of the measure will be, that the contracts generally will be made with the Union medical officers, and not with the profession at large. Amongst the guardians there is naturally a bias in favour of the medical men who are employed by the parish. The remuneration itself cannot be an object to any one, apart from the collateral circumstances, such as the introduction to practice, and the publication of the vaccinator's name in the document which the Deputy Registrar hands to the parents of all children born within the parish. Dr. Webster thought the Act calculated to have an injurious effect upon private interests: at all events, it is calculated to create and foster jealousies and heartburnings between medical men. He should like to see union and fraternal feeling existing amongst members of the same profession; therefore, he looked unfavourably upon the new Vaccination Act. It is very crudely put together, and not at all such a measure as a little more time might have produced.

The PRESIDENT. Who has the nomination of the vaccinator?

Dr. WEBSTER. The guardians of the parish. He almost considered that there was a breach of faith with the Vaccination Committee of this Branch. They had had an interview with Lord Palmerston, and he seemed to promise that the measure should not pass last session; but it was passed through the House of Commons, perhaps against the minister's wish, and carried through the House of Lords in a very sudden manner, so that the profession could not be roused to oppose it. This showed at once the want of a representative Council, to which we could apply at any time to bring forward our grievances. This great Association ought to be a centre of union where advice and counsel might be had, and where great things might be done as regarded subjects of importance in medical polity, medical ethics, and scientific questions; but he felt that, in the present constitution of the Association, we had not the benefit which he trusted before long we should have, of a better internal regulation. The Council at present is so scattered abroad, and so irregularly distributed, that it is unworkable; therefore it falls far short of what it might do, if it were put in a more efficient state. He was almost at a loss to know what course to take with this measure. One does not like to fly in the face of an Act of Parliament; but, unless a firm stand be made, we shall have other grievances put upon us. He had therefore drawn up these resolutions, which he would now read:—

"1. That while the Metropolitan Counties Branch of the Provincial Medical and Surgical Association recognises the propriety of a compulsory vaccination Act, which shall be salutary to the public and just to the profession, it cannot but highly disapprove of the Act passed in the late Session of Parliament.

"2. That the amount of compulsory gratuitous medical service

inflicted by this measure, is vexatious, onerous, and unjust; and while the benevolent and unrequited labours of the medical profession will bear ample comparison with those of any other profession, this Branch believes that the time has arrived, when a firm and united stand must be made for the protection of its members and their medical brethren against the late and similar encroachments on their just rights.

"3. That the Vaccination Act being contrary to the political rights of the subject, by requiring important services without remuneration, this Branch considers that the law in its present state will be found impracticable, and recommends the adoption of the most energetic measures for its amendment or repeal.

"4. That a Committee be appointed to wait on Her Majesty's Prime Minister and the Home Secretary, and to adopt such other proceedings with reference to the Vaccination Act as may appear necessary."

It might be a question whether counsel's opinion should not be taken upon the working of this Act, as to how far the government, by putting it into the hands of the Registrar General, have made themselves liable for the expenses which may be incurred. Another thing to be considered, was, whether a case before a county court should not be tried, by way of ascertaining exactly how the matter stands. This might seem a paltry matter of pounds, shillings, and pence. He did not care for any obloquy which might be cast upon him: he brought the matter forward chiefly for the sake of his younger brethren, and on public grounds.

Mr. RICHARDSON in seconding the foregoing resolution, said that he quite agreed in the remarks which had been made by Dr. Webster. He (Mr. Richardson) found the operation of the Act very mischievous. Small tradesmen's wives expected their children to be vaccinated free; and if the medical man refused, they took the children to the public vaccinator, who was paid by the parish, and in many cases he retained them as patients. In his view, the Act was quite unconstitutional, and the parish had no more right to ask for these certificates gratis, than they would have to ask a carpenter to repair the church. It might happen that a child required to be vaccinated six or seven times; and one thing required was impracticable, namely, a certificate that a child was not susceptible of the vaccine disease. Let the meeting imagine how many times a child must be vaccinated, without fee or reward, to prove insusceptibility. He thought there was a very great necessity for appointing a deputation to the Home Secretary upon the subject.

The resolutions were carried unanimously.

It was moved, seconded, and carried unanimously

"That the Committee consist of the following gentlemen: The President, the President-Elect, the Secretary, Dr. Cormack, Dr. Fraser, Dr. Semple, Dr. Webster, and B. W. Richardson, Esq.; with power to add to their number."

PAYMENT OF SUBSCRIPTIONS. The Law of the Provincial Medical and Surgical Association is as follows:—

"Each Member of the Association shall pay One Guinea annually: the Subscription to commence from the 1st of January in each year, and to be considered as due, unless notice of its being withdrawn be given to the Secretary or Secretaries antecedently to the year for which it would be payable; for such Subscription each Member shall receive a copy of all publications issued for the general use of the Members of the Association."

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. LI.

LONDON: FRIDAY EVENING, DECEMBER 23, 1853.

NEW SERIES.

STUDENTS' MEDICAL SOCIETIES.

Among the subsidiary plans connected with the improvement of medical education, there are none so generally neglected, and yet none more useful, than the formation of medical debating societies. Probably there is nothing more calculated to develop quickness of thought, or ready power of clothing it in appropriate language, as well as to inspire a wholesome respect for the talents of others, than assisting regularly at the meetings of such a society. As types of the class of societies to which we allude, the venerable Royal Medical Society of Edinburgh, and the old (but, alas! now defunct) Physical Society of Guy's, present themselves to the mind. How many of our readers can reflect with delight on the old associations of the former, during their residence as students in the modern Athens! How many can gratefully look back to the Friday evenings of bygone years, when they listened and took part in the discussions held within the famous Old Hall in Surgeon Square! How many can remember with grateful consciousness that there first germinated that zeal, which has since borne the good fruits of an honourable position and a respected name!

The happy admixture of senior and junior students—of those, whose associations are all future, and of those, who are prepared to take part in the battle of life in earnest—constitutes one of the peculiar characters of such societies as we have referred to. In a society composed exclusively of their seniors, and in which they alone, save by a special act of courtesy, are allowed to discuss the merits of the papers read, the students may indeed *listen* with advantage. Still, the advantage can be only of the passive kind. To derive the full amount of benefit from the debate, the student must feel himself to be an actor in the scene. If he be not conscious that he is an integral part of the society, zealous for its reputation, and anxious for its usefulness, he is apt to become a listless attendant, or, what is far worse, an imperfect critic.

The task of preparing a paper calls upon the student for much more real and profitable work than would be imagined by those who have never undertaken such an effort when *in statu pupillari*. He has not only to call upon all his own resources, but to consult the opinions of all the authorities who have recorded anything worth consulting. Thus a large mass of matter (sometimes crude and undigested, it must be confessed), is often collected. The subsequent task of throwing this into a proper form, examining opposing opinions, and condensing all into the limits of a half-hour's essay, constitutes a mental exercise of no small value. From his previous attendance at the society, he has become somewhat acquainted with some of the peculiar views of the most favourite speakers; hence he has to fortify his own views against their assault, and to prepare for a reply. We are not too old to forget confidential revelations made to us by our foremost comrades, on the eventful occasion of their reading a first paper. We could from truthful reminiscences describe the nervous anxiety,

the sense of the heart becoming suddenly too large for the chest, and the sincere desire for the moment to change places with the janitor. But how entirely were these feelings replaced by calm confidence, when, on finishing the task, words of encouragement or friendly criticism fell from the debaters.

A student is thus taught his own deficiencies, while at the same time he is led to cultivate and place more confidence in his own powers. His respect for his more accomplished fellow students excites an honourable ambition; and a knowledge that the idle have neither welcome nor place in the society stimulates his industry.

Several of the medical schools of the metropolis have now a student's debating society attached to them; but it could be wished that such institutions were more general. There is, however, too often a flatness and want of interest in the debates of some, on account of the students for the most part reflecting the opinions only of their own teachers. Hence a pupil's society, where the students from all the medical schools in the metropolis could assemble, would, if well organised, be a very great addition to the educational resources of our profession in London. The opinions held by the professors and officers of the different schools and hospitals would become better known to the young aspirants; and much of the spirit of unhealthy rivalry, which too often exists, would be softened down and exchanged for mutual respect and confidence.

THE NEW LUNACY ACTS.

THE majority of our readers are aware that, in the last sessions of Parliament, certain alterations were made in the laws relating to the care and treatment of lunatics; and that these came into force on the 1st of November.

One of the most important of these alterations refers to the *manner of wording a medical certificate* authorising the reception of a patient into a lunatic asylum. A medical certificate of insanity being an instrument by which a person may be deprived of liberty, is warily guarded by the law, and rightly placed under very stringent regulations. These regulations are duly set forth in the new "Lunatics' Care and Treatment Act", and have been further explained in a circular of instructions lately issued by order of the Commissioners in Lunacy; but, as many members of the ASSOCIATION may not have seen either of these documents, a few words concerning "medical certificates" may not be misplaced in our pages.

That the instructions appended to the common printed form of certificate, are not sufficiently clear or explicit, is presumable from the fact that a superintendent of a large asylum informs us that he has rarely received a certificate worded as the law requires, since the new Act came into operation. The following are the points to which the attention ought to be directed:—

1. It is not sufficient for a medical practitioner to state simply that he is a physician, surgeon, or apothecary; he must specify at length the *legal qualification*,

- diploma, or license, which entitles him to practise medicine in the United Kingdom.
2. He is required to state, in full, not only the name of the patient, the date of his examination, and the place where the examination took place, but also the habitual place of residence, and profession or occupation (if any) of the patient.
 3. When two or more medical certificates are required (as is always the case with private patients), he must examine the patient "separately from any other medical practitioner"; and state the fact of his having done so in his certificate.
 4. It is indispensably necessary for him to state the fact or facts indicating insanity, *observed by himself*; for a certificate founded *only* upon facts communicated by others, is invalid, and does not authorise the reception of a patient into any lunatic asylum. When the facts observed by the medical practitioner himself are so strong as to leave no manner of doubt as to the patient's insanity, the certificate is valid without the insertion of facts communicated by others. Nevertheless, when additional facts can be obtained, they should be stated in confirmation; and it is then necessary to name and specify the person who communicated them.
 5. The medical certificate need not be written on the day of the patient's examination, but at any time within seven clear days afterwards. The dates of the examination and of the signature must both be given.
 6. A Pauper Lunatic may be received into an asylum with one medical certificate; and the medical officers of unions or parishes are no longer prohibited from signing certificates of pauper lunatics belonging thereto.

The following certificates will serve to exemplify the preceding instructions, the portions in italics being those which the medical practitioner has to write in filling up the usual form.

"I, the undersigned, *William Heberden*, being a *Doctor of Medicine of the University of London*, and being in actual practice as a *Physician*, hereby certify that I, on the *tenth day of December 1853*, at *Fulton Terrace, Birmingham*, in the county of *Warwick*, separately from any other medical practitioner, personally examined *Mr. James Henry White*, of *Fulton Terrace, Birmingham*, gentleman, and that the said *James Henry White* is a *lunatic*, and a proper person to be taken charge of, and detained under care and treatment; and that I have formed this opinion upon the following grounds, viz.:

"1. Facts indicating insanity observed by myself: *His language was altogether incoherent and irrational; he was extremely noisy and excited, shouting, singing, and swearing incessantly; he threatened me with personal injury, and attempted to strike me.*

"2. Other facts (if any) indicating insanity, communicated to me by others: *Helen White, wife of the said James Henry White, informed me personally, that he had been in the state in which I saw him for three days and nights, with scarcely any variation.*

"Signed, name, *William Heberden, M.D.*

"Place of abode, *London St., Birmingham.*

"Dated this *tenth day of December*,

One thousand eight hundred and fifty-three."

"I, the undersigned, *James Purdey Cooper*, being a *Fellow of the Royal College of Surgeons of England*, and being in actual practice as a *surgeon*, hereby certify that I, on the *tenth day of December 1853*, at *No. 14, New Orleans Street, Manchester*, in the county of *Lancaster*, separately from any other medical practitioner, personally examined *Mrs. Mary Smith, wife of John Smith, Esq., cotton manufacturer, of*

No. 14, New Orleans St., Manchester; and that the said *Mary Smith* is a *person of unsound mind*, and a proper person to be taken charge of, and detained under care and treatment; and that I have formed this opinion upon the following grounds, viz.:

"1. Facts indicating insanity observed by myself: *She told me that God had forsaken her on account of her wickedness, and that Satan was coming that same night to carry her off, together with her husband and children.*

"2. Other facts (if any) indicating insanity, communicated to me by others: *Mr. J. Smith, husband of the said Mary Smith, personally informed me that, up to the beginning of last November, she was tranquil, happy, and always religiously disposed; that last night she attempted to strangle herself with a bell-rope.*

"Signed, name, *James Purdey Cooper.*

"Place of abode, *Queen Square, Manchester.*

"Dated this *tenth day of December*,

One thousand eight hundred and fifty-three."

"I, the undersigned, *Thomas Cheselden*, being a *Member of the Royal College of Surgeons of England and a Licentiate of the Apothecaries' Company*, and being in actual practice as a *Surgeon and Apothecary*, hereby certify that I, on the *twelfth day of December, 1853*, at *Newland Hall, in the parish of Hawtree, in the county of Essex*, separately from any other medical practitioner, personally examined *Miss Jane Thomson, daughter of the late Alexander Thomson, of Colchester, solicitor*, and that the said *Jane Thomson* is a *person of unsound mind*, and a proper person to be taken charge of and detained under care and treatment, and that I have formed this opinion upon the following grounds, viz.:

"1. Facts indicating insanity observed by himself: *She has a vacant, unmeaning expression of countenance; seems incapable of answering questions or conversing in a rational manner; frequently laughs without a cause. At the time of my visit she was nursing a doll, and told me it was an angel.*

"2. Other facts (if any) indicating insanity communicated to me by others: *Mrs. Burton, of Newland Hall, sister of the said Jane Thomson, informed me personally that she neglects to take proper care of her person: that when interfered with or offended she becomes noisy, uses bad language, and tears her clothes.*

"Signed, name, *Thomas Cheselden.*

"Place of abode, *Colchester, Essex.*

"Dated this *fifteenth day of December*,

One thousand eight hundred and fifty-three.

Some of the new regulations are open to criticism, particularly that which relates to the *personal observation* of the facts indicating insanity. We have received some important remarks upon this subject from a member, which we reserve for another number.

PROSPECTS OF THE PROFESSION.

LORD PALMERSTON has unexpectedly retired from the Cabinet Council of Her Majesty. It is supposed that he has resigned from dislike to the Representation Reform Bill, which his late colleague, Lord John Russell, is to bring into Parliament. As regards the prospects of our profession, they are not likely to be prejudiced by what has taken place; for to medical questions Lord Palmerston had never greatly bent his mind.

It is generally understood, that in Lord John Russell's Parliamentary Representation Bill, members are to be given to the Universities of London and of Edinburgh; and if judicious efforts be made, some degree of representation may likewise be conceded to the Medical profession. The profession ought to be prepared when the proper time arrives, to state its views on this important subject. Parliament must be told that, the giving of members to the Medical Corporations as at present constituted, would be parallel to vesting the representation of the city of London in the Common Council, a body which bears the same relation to the mass of citizens as do the Colleges to the mass of Medical practitioners—the relation of antagonism.

ORIGINAL COMMUNICATIONS.

ON THE SOURCE OF HÆMORRHAGE IN
PARTIAL SEPARATION OF THE
PLACENTA.

By F. W. MACKENZIE, M.D.Lond., Fellow of University
College, London.

(Read before the Medical Society of London, Dec. 17, 1853.)

THERE are few subjects in obstetric medicine of greater scientific interest, and none of greater practical importance, than that of the anatomical source of hæmorrhage in cases of partial separation of the placenta. Upon its right understanding may be said to depend not only the whole question of the extraction of the placenta, in cases of placenta prævia, but also the general treatment of uterine hæmorrhage in all its several forms; and yet there is probably no subject upon which so much diversity of opinion prevails, or in regard to which mere speculative notions have been more freely allowed to take the place of original observation. With the view of aiding in the solution of this question, I am induced to submit to the Society some investigations which were specially undertaken for the purpose of elucidating it.

On referring to the published writings of various obstetric authorities, it will be found that three different opinions prevail at the present day respecting the anatomical source of hæmorrhage in cases of partial separation of the placenta. The first affirms, that it is principally or wholly uterine; the second, that it is principally or wholly placental; the third, that it is both uterine and placental, the blood escaping partly from the exposed uterine, and partly from the detached placental surfaces.

Further, it will be found that uterine hæmorrhage, whether occurring in connection with partial or entire separation of the placenta, is generally considered to be principally venous. "Uterine hæmorrhage," says Dr. Simpson, "after the separation of the placenta, in any of the stages of labour, is *not arterial* in its character. The utero-placental arteries are numerous, but so long and slender as to become readily closed; first, by the tonicity of their coats; secondly, by contraction of the uterine fibres upon the course of these vessels themselves, as they pass through and amid the uterine structure; and thirdly and principally, by the changes in their tissues produced by the mechanical rupture of their coats,—*torn arteries* being little, if at all, liable to bleed, and the placenta being separated by a true process of *avulsion*. "When the placenta is only separated," says Dr. Radford, "the blood which is lost is chiefly venous." "When the placenta is separated partially from the uterus," Dr. Murphy observes, "any hæmorrhage must arise chiefly from the broken veins, and not from one but from both of their divided extremities." "It is," says Dr. Robert Lee, "from the great semilunar valvular-like venous openings, in the lining membrane of the uterus, and of the arteries which are laid open by the separation of the placenta, that the blood alone flows in uterine hæmorrhage." I have made these quotations for the purpose of showing, that the question at issue is one of a very complex character. It is one which has reference, not only to the organ from whence the blood escapes, but to the particular system of vessels from which it is poured out also.

On reflecting upon these circumstances, I was led to believe that some light might be thrown upon the question, by ascertaining experimentally the source of hæmorrhage in an animal whose placenta, like that of the human female, was both decidual and fetal. A pregnant bitch was accordingly obtained, which had nearly completed the full period of gestation: and it having been placed under the influence of chloroform, the uterus was exposed and opened, and the following observations were made.

I. It was observed, on separating the placenta, that blood flowed freely and continuously from the denuded uterine surface, increasing with the detachment, whilst none escaped from the detached portion of the placenta.

II. That the blood which escaped from the uterus was distinctly arterial, being of a bright arterial character.

III. On rupturing a placenta whilst still partially adherent to the uterus, it was found that a small quantity of dark venous blood escaped from the part torn; but only to a very trivial extent.

These observations were made with different placenta, and uniformly with the same results.

Thus it would appear, in the canine species, that the source of hæmorrhage in cases in which the placenta is partially detached, is exclusively the denuded uterine surface, so long as the placenta is entire: that the hæmorrhage which takes place is of an arterial character; and that although a certain amount of blood may escape from the placenta, if lacerated or torn whilst still partially adherent, yet that this is very trivial in quantity, and of a dark venous character.

Considering, however, the different distribution of the veins in the maternal portion of the placenta in the human and canine species, I am aware that this experiment cannot be regarded as decisive of the source of hæmorrhage under similar circumstances in the former. We know, for instance, that in the human placenta, the utero-placental arteries open into large cells or dilated capillaries in the maternal portion of the organ, between which a free intercommunication exists; whereas in the bitch, the venous vessels of the maternal part of the placenta do not constitute a cellular or cavernous structure, but in form and distribution resemble ordinary veins. These circumstances were particularly pointed out by Dr. Sharpey, to whom I communicated the results of the experiment I have related; and in the course of a subsequent conversation he observed that, in his opinion, the best mode of ascertaining the source of hæmorrhage in partial separations of the placenta in the human female, would be to obtain a uterus to which the placenta was still partially adherent, to inject the hypogastric arteries with defibrinated blood, and to observe whether it escaped from the uterus, the placenta, or from both.

In the early part of April 1853, I had an opportunity of carrying out this suggestion. A poor woman under the care of Messrs. Clark, Norway, and myself, died of hæmorrhage during the progress of a labour, rendered protracted by malposition and impaction of the fetal head. A *post mortem* examination of the body was made on the following day, and as it was found that the placenta was still partially adherent, although much of it had been detached, it appeared to me that it would serve the purpose in view. Accordingly the uterus and placenta were removed to University College, where the following observations were made under the immediate superintendence of Dr. Sharpey.

The uterus, which had been cut off somewhere above its orifice, was first carefully inverted, and several loose unadherent coagula were removed from its interior. It had the appearance of being very exsanguine; and on the surface from which the placenta had been detached, the ramifications of the utero-placental arteries could be plainly seen, but free from any plugging or coagula; about a fifth of the placenta was still adherent. In the next place, the vessels along the cut surface of the uterus were secured by ligatures placed along the line of its division, and the hypogastric and ovarian veins were also secured by ligature. An injecting pipe was now fixed in one of the hypogastric arteries, and some defibrinated blood was steadily injected. The results of the operation were as follows. The blood escaped freely from the orifices of the utero-placental arteries, which had been torn across by the separation of the placenta; none escaped from the torn utero-placental veins, nor did any pass away from the placenta. The injection was continued for some time, but with no variation in the results. It was now thought advisable to ascertain the force with which the blood was injected; and tested by the hæmadynamometer it was found not to exceed that of the heart, acting under ordinary circumstances. In the next place, the opposite hypogastric artery was injected; and in this case it was found, as in the other, that blood escaped freely from the orifices of the torn utero-placental arteries, that

none passed out of the torn utero-placental veins; whilst in this case a small quantity escaped from the surface of the placenta, contiguous to that which was still adherent. The injection was repeated several times with the same results; the great bulk of the injected blood escaped readily from the orifices of the torn utero-placental arteries, a small quantity only came from the placenta, whilst none could be observed to pass out from the torn utero-placental veins, whose orifices were plainly visible and carefully watched. Nor, it should be added, were the vessels plugged with coagula.

Looking then to the results of this experiment, it would appear that the source of hæmorrhage in partial but extensive separations of the placenta is principally uterine, and only slightly placental, and further, that it is arterial rather than venous. It would, however, be too much to assume that the experiments are conclusive as to the source of hæmorrhage in all cases of placental separation. It must be remembered, that in this case the placenta was very greatly detached, and as, consequently, little blood only could have entered it, much could not be expected to have escaped from it; whilst, again, the tonicity of the arterial system could not have been great during life, as evidenced by the little resistance offered by the utero-placental arteries to the escape of the blood injected. Admitting however the full force of these and other considerations, it yet appears to me that the results of this experiment, coupled with those of the one previously related, and taken in connection with various clinical facts, afforded strong grounds for the belief that the principal source of hæmorrhage in cases of partial separation of the placenta is uterine rather than placental, and arterial rather than venous.

What then may be asked are the grounds upon which it is affirmed that these hæmorrhages are respectively either venous or placental? The best reply to this question is probably that given by Dr. Simpson, in the passage I have quoted from his writings. "Uterine hæmorrhage," he observes "after separation of the placenta in any of the stages of labour, is not arterial in its character, because the utero-placental arteries are so long and slender as to become readily closed: 1. By the tonicity of their coats. 2. By contraction of the uterine fibres upon them. 3. Principally by the changes in their tissues, produced by the mechanical rupture of their coats." These probably constitute the entire grounds upon which the opinion in question is maintainable; and I will therefore proceed to consider respectively their nature and validity.

I. The assertion "*that uterine hæmorrhage after the separation of the placenta in any of the stages of labour, is not arterial in its character,*" is one which, so far as I am aware, is not only unsupported by any evidence, but directly at variance with many trustworthy observations. On the 23rd of September, 1853, I had an opportunity of investigating this point, and of satisfying myself that the hæmorrhage which took place from the uterus, between the birth of the child and the expulsion of the placenta, was distinctly of an arterial character. On the 10th of October, 1853, whilst in attendance upon a case of labour, my attention was directed to a rather profuse flow of blood which followed the birth of the child; and I observed, as it passed over the vulva, that whilst the greater part was of a bright arterial colour, a small portion was of a dark venous hue; the striking difference in the colour of the two portions left no doubt in my mind that they were respectively arterial and venous. The same thing was observed in the experiment I have related, in which the placenta was detached from the uterus of the bitch. The blood which flowed freely from the denuded uterine surface was of a bright florid colour, and such as to convince both Mr. Marshall and myself that it was arterial. I further find that the observations I have myself made, as to the character of the blood lost in uterine hæmorrhages, are similar to those which have been made by other medical men; and therefore, in the absence of any evidence to the contrary, we may, I think, conclude that uterine hæmorrhage after the separation of the placenta is rather of an arterial than a venous character.

II. The second point affirmed is, "*that arterial hæmorrhage from the uterus is prevented by the tonicity of the utero-placental arteries*". It is far from my intention to assert that, in a state of health and tranquillity of the circulation, this is not the case; but, under other circumstances, it may be doubted whether the principle in question can be relied upon for the attainment of this object. The tonicity of the arteries, like every other vital property, is liable to be modified or affected by a variety of circumstances; and, regarded as a modification of the principle of contractility, may be supposed to be influenced by the same general causes; to be increased by those which tend to augment the strength and vigour of the body, diminished by those which tend to enervate or exhaust it, and disturbed by those which tend to disturb the nervous and vascular systems. Now, if we consider the circumstances under which uterine hæmorrhages are most liable to occur, we shall find that they are respectively those which tend to enervate or exhaust the constitutional powers on the one hand, or morbidly excite or disturb the vascular system on the other. One of the most alarming cases of *post partum* hæmorrhage which I have ever witnessed occurred in the wife of an eminent obstetric physician, whose nervous system and energies had been prostrated by the unexpected death of her mother about three weeks before the accession of labour. The poor woman, whose uterus was the subject of the experiment I have related, died of internal hæmorrhage consequent upon partial separation of the placenta, when her strength had been exhausted by long parturient efforts; and numerous cases are related of fatal hæmorrhages occurring in women who had been previously anæmic and weakly. On the other hand, every practitioner must have met with profuse uterine hæmorrhage in connexion with morbid excitement of the heart and circulation; and hereafter it will be shown that, of the causes of such excitement, some have a sympathetic, and others a direct mode of operation. Further, I may appeal to the condition of the utero-placental arteries in the case of the patient who died of uterine hæmorrhage, as showing that no plugging or particular contraction of them had taken place during life. Here indeed was a physical demonstration of the condition of these vessels, as they must have existed during life, after fatal hæmorrhage consequent upon partial separation of the placenta, the placenta having been separated during life; and if it can be clearly shown, as it was, that they had neither been so contracted or plugged during life as to prevent the escape of blood from them when injected with no more force than that of the heart's action after death, then it must follow, that neither could they have prevented the escape of blood from them during life, when injected under the ordinary force of the circulation. On these grounds, then, we may venture to doubt the correctness of the dogma, that the tonicity of the uteroplacental arteries is, under all circumstances, capable of preventing the escape of blood from their orifices when torn across by the separation of the placenta.

III. In the next place, it is affirmed, "*that hæmorrhage from the utero-placental arteries is prevented by contraction of the uterine fibres upon the course of these vessels, as they pass through and amid the uterine structure*"—a doctrine which is manifestly at variance with the well known fact, that there is often no direct relation between the degree of uterine contraction and the degree or tendency to uterine hæmorrhage. "The observing practitioner," says Dr. Gooch, "must have been frequently struck by the little proportion that existed between the want of contraction and the degree of hæmorrhage; having found the uterus bulky without any hæmorrhage, and a profuse hæmorrhage without greater bulk of uterus. Nay, further, I have witnessed a profuse hæmorrhage, though the uterus had contracted in the degree which commonly indicates security; and I have ventured to do what is seldom justifiable, separate the placenta before the uterus had contracted, without more hæmorrhage than after a common labour." The correctness of these remarks, and their pertinency to the question under consideration, must, I think, be generally admitted;

but, besides these, two other series of facts may be adduced, in opposition to the doctrine above propounded. First, that, in several instances, the placenta has been spontaneously or artificially separated from the uterus before the birth of the child, and, consequently, under circumstances in which contraction of the uterus could not take place, without any hæmorrhage supervening; and, secondly, that, when it has been attached to the os and cervix uteri, its separation has been effected in many cases without any particular hæmorrhage resulting, although it is affirmed by some anatomists, that there are few or no contracting fibres in the structure of the os and cervix uteri.

IV. The last proposition affirmed—"that hæmorrhage from the utero-placental arteries is prevented by the changes in their tissues produced by the mechanical rupture of their coats, torn arteries being little or at all liable to bleed, and the placenta being separated by a true process of avulsion"—is completely invalidated by the results of the experiment performed upon the pregnant bitch, which I have described in the former part of this paper; for, on detaching the placenta from the uterus, and thereby lacerating or tearing through the utero-placental arteries, arterial hæmorrhage was observed to follow. That is to say, having separated the placenta by a true process of *avulsion*, it was demonstrated that such proceeding was not productive of those changes in the torn coats of the utero-placental arteries which are assumed to follow such operation, and by which, it is alleged, arterial hæmorrhage is prevented. And, to appreciate the full force and importance of this fact to the present inquiry, it is necessary to bear in mind that the placenta of the canine, as of the human species, possesses a maternal as well as a fetal portion; that the utero-placental arteries in both pass from the uterus into the maternal portion of the organ, as do the utero-placental veins from the latter to the uterus; and that the chief difference in the anatomical structure of the two organs consists in the different distribution of the veins in their maternal portions. Accordingly, it must follow, that a separation of the placenta must equally give rise to a laceration of the utero-placental arteries in both species; and if it is clearly shown that hæmorrhage from these arteries is not thereby prevented in the one, it must follow that it cannot thereby be prevented in the other.

I have thus critically examined the several grounds upon which it is alleged that hæmorrhage does not occur from the torn utero-placental arteries in cases of partial separation of the placenta; and, having shown the insufficiency of the data upon which this doctrine has been assumed, I proceed to observe, that if blood does actually escape from these vessels, it must follow that proportionately little will escape from either the uterine veins or the placenta; because, according to the well known laws of hydraulics, fluids circulating in closed vessels will only continue in their regular course when due pressure is maintained upon them. Now, under the circumstances stated, this condition is not fulfilled; and, accordingly, the greater part of the blood entering the utero-placental arteries will escape from their open orifices, rather than be continued onwards into either the uterine veins or placenta. In this respect, it must be borne in mind that the character of the utero-placental circulation must materially differ before and after separation of the placenta. In the former case, the pressure upon the circulating blood is equalised throughout; whereas in the latter, it is unequally distributed, and accordingly there will be a tendency to hæmorrhage where this pressure is removed, or wherever openings exist in the utero-placental arteries.

The correctness of this view is further supported by a variety of circumstances, which go far to prove that the principal source of hæmorrhage in these cases is neither the uterine veins nor the placenta. As opposed to its placental origin, I may mention: First, the character of the blood lost; which, as I have stated, is principally arterial, rather than venous. Secondly, the rapidity with which the blood escapes, and its fluidity in many cases of puerperal hæmorrhage, would tend to show that it was rather poured out directly from the utero-placental arteries, than indirectly from

the placenta. Thirdly, the peculiar cellular, cavernous, or reticulate structure of the maternal portion of the placenta, may be referred to as being calculated to prevent placental hæmorrhage, by producing stagnation and coagulation of the blood in this part of the organ, when separated from its vascular connexion with the uterus. Fourthly, the occurrence of profuse hæmorrhage after the entire separation of the placenta, both before and after the birth of the child, may be referred to as showing that it has no necessary dependence upon this organ. Fifthly, the small amount of blood which escaped from the placenta when the utero-placental arteries were injected in the experiment I have related, affords strong evidence against the placental origin of these hæmorrhages. Whilst, sixthly, the escape of blood from the orifices of the torn utero-placental arteries, by lessening the quantity of blood which would otherwise enter the placenta, affords an additional argument against their placental origin.

As opposed to the venous origin of the hæmorrhage, I may adduce the following facts: First, that the blood lost is for the most part not venous. Secondly, the absence of hæmorrhage in many cases, in which those conditions exist which are most favourable to the occurrence of venous hæmorrhage, namely, relaxed and distended states of the uterus. Thirdly, the absence of hæmorrhage in many cases in which the placenta has been attached and separated from the os and cervix uteri; where the contractile mechanism of the uterus does not exist, by which it is alleged venous hæmorrhage is prevented. Fourthly, the occurrence of profuse hæmorrhage when the uterus is contracted, and when consequently the uterine veins must be firmly compressed. Fifthly, the escape of blood from the orifices of the torn utero-placental arteries; which would equally tend to prevent venous as well as placental hæmorrhage. Sixthly, the fact that no blood was observed to flow from the uterine veins when the utero-placental arteries were injected in the experiment I have related. Seventhly, the normal course of the uterine circulation being from the uterine veins to the vena cava, it must follow that venous hæmorrhage can only occur as the result of a retrograde, and consequently abnormal, movement of the blood.

Upon the whole, then, two things would appear to be certain: first, that no *necessary* relation exists between the degree of hæmorrhage and the degree of separation of the placenta; or, secondly, between the degree of hæmorrhage and the degree of contraction of the uterus; uterine hæmorrhage having been variously moderate or excessive under similar degrees of separation of the placenta, and similarly moderate or excessive under the opposite conditions of relaxation and contraction of the uterus. Can it then be doubted that the absence of, or disposition to uterine hæmorrhage must depend, in many cases, upon other causes than the anatomical connection of the placenta with the uterus on the one hand, or the contractile mechanism of the uterus on the other; or further, that these are to be sought for in the occurrence of arterial hæmorrhage, and the various conditions of the utero-placental arteries, as modified by the general condition of the arterial system? Bearing in mind this view of the case, we can understand how it may happen that, the tonicity of the arterial system being great, uterine hæmorrhage may be prevented when the uterus is most relaxed and when consequently the conditions most favourable to venous hæmorrhage exist; that under the influence of morbid excitation of the heart and arteries, it may be profuse when the uterus is contracted, and when, consequently, venous hæmorrhage would be most effectually prevented; and that its degree may vary in different cases with the same amount of separation of the placenta. Let me however be distinctly understood as speaking of *pathological*, rather than of *physiological* puerperal hæmorrhage, and of its *principal*, rather than of its *exclusive* source; because on the one hand, it can scarcely be supposed, that the placenta can be separated from the uterus, under the most favourable circumstances in child-birth, without some hæmorrhage resulting, which therefore cannot be regarded as pathological; nor, on the other, can it be supposed that

such hæmorrhage should be derived exclusively from the torn utero-placental arteries. It has indeed been experimentally shown that some blood does actually escape from the detached portion of the placenta when the hypogastric arteries are injected, and the quantity so escaping will doubtless vary in different cases, and I have referred to an observation in which venous blood was discharged mixed with arterial, in a case in which hæmorrhage preceded the expulsion of the placenta. It is therefore highly probable, that in all cases the source of hæmorrhage is of a mixed character. But, looking to its source in those which are so considerable as to endanger the safety of the patient, it appears to me that the facts adduced are sufficient to justify the conclusion that it is principally arterial; and that, although blood may simultaneously escape from the utero-placental veins and placenta, the quantity lost by these channels considerably falls short of that which escapes from the torn utero-placental arteries.

In conclusion, we may, I think, deduce from a consideration of these facts some rules of practical importance in the treatment of puerperal hæmorrhages, whether occurring in connection with partial or complete separation of the placenta. In particular, we may learn the importance of treating them upon broader principles than those derived from a consideration of the condition of the uterus or the degree of separation of the placenta; and the necessity of investigating carefully the physiological and pathological states of the nervous and vascular systems, both before and during labour, with a view to the adoption of measures of a preventive, as well as curative character. It is not my intention to enter at length upon this subject; but a brief reference to the principles upon which the prevention of puerperal hæmorrhage should be attempted, will not be inconsistent with the object of this paper.

Apart from the anatomical condition of the uterus and placenta, it will be found in practice that hæmorrhage during labour is liable to be excessive, in connection with two opposite states of the vascular system. In the one, there is morbid excitement of the heart and arteries, directly or sympathetically induced; in the other, there is a state of extreme depression of the circulation dependent either upon atony of the blood vessels, or an impoverished condition of the blood. As both these conditions may exist and be recognised before the accession of labour, I will briefly advert to the curative indications they suggest.

Hæmorrhage occurring during labour, in connection with inordinate excitement of the circulation, has been well illustrated by Dr. Gooch, as well as the treatment it requires, in his paper on a peculiar form of hæmorrhage from the uterus. The patient before the accession of labour was flushed, and had a very full quick pulse. Abstinence from meat, wine, and warm drinks, a cool room, and a saline purgative, diminished but did not remove this state of the circulation, which continued in a considerable degree when the child was born. It was expelled very gradually, and after the removal of the placenta the uterus felt contracted in the ordinary degree. Nevertheless about twenty minutes afterwards, there came on one of the most frightful hæmorrhages which, Dr. Gooch observes, he had ever witnessed. Twelve months afterwards he attended the same patient in a subsequent labour, and was struck on observing the same state of circulation which had preceded the first. The labour proceeded naturally, but was again followed by profuse and alarming hæmorrhage. Reflecting upon these facts, Dr. Gooch was led to believe that the hæmorrhage depended not upon want of contraction of the uterus, but on want of tranquillity of the circulation; and he concluded if she again became pregnant, that a mode of treatment which would cause her to fall in labour with a cool skin, and quiet pulse, would be the best means of preventing a recurrence of the accident. In due time he had an opportunity of testing this practice; and although in the first instance he was unsuccessful, yet in another, by means of an abstemious diet, saline aperients, and the moderate abstraction of blood from the arm before delivery, the

labour was completed without the smallest degree of flooding or faintness. The principle upon which this variety of uterine hæmorrhage should be treated, is sufficiently indicated in these details.

In a second series of cases, it has appeared to me that hæmorrhage during labour has been immediately dependent upon a disordered state of the circulation, excited by functional derangement of the liver and digestive organs. Such patients suffer for some time before labour, from constipation, flatulence, and other symptoms of indigestion; and if the stools are examined, they are found to be of a pale, or clay colour.

Profuse hæmorrhage under these circumstances may either immediately follow the birth of the child, or may continue to recur for some time after labour. In two instances recently attended by me, profuse hæmorrhage followed delivery; and in both the state of the hepatic functions, was such as I have described. The recurrence of hæmorrhage led to an examination of the stools; in each case they were found to be clay coloured, and almost destitute of bile; and on restoring the action of the liver, the disposition to hæmorrhage was in each case removed. From these facts I have been led to believe, that many instances of puerperal hæmorrhage might be prevented by inquiring into the condition of the liver and digestive organs before labour, and adopting such means as would rectify any derangement which might exist.

The second class of cases I have referred to, are those in which puerperal hæmorrhages occur in connexion with an enfeebled state of the circulation; and this, inasmuch as it may have existed long antecedently to labour, is eminently amenable to preventive measures of treatment. It is met with in females whose physical health has been deteriorated or depressed by bodily disease, laborious or unhealthy occupations, or mental anxiety, and comprehends a very numerous category. In these, either from atony of the blood vessels, or an extreme fluidity of the blood, but little or no barrier is opposed to the escape of this fluid; and if preventive treatment has not been adopted, but little good will sometimes result from any other. In all such cases the treatment should be of a prospective character, and directed to the improvement of the health before labour by the employment of such measures, hygienic and medicinal, as will amend the condition of the blood and augment the tone and vigour of the arterial system. In proportion as anæmia preponderates, iron will be indicated; where atony of the nervous and vascular systems is the more prominent condition, strychnia should be preferred; whilst in cases in which both these pathological elements coexist, a combination of both remedies will answer best.

As regards curative treatment, I would wish more especially to direct attention to the advantages likely to be derived from the employment of galvanism in these cases; not, indeed, locally applied to the uterus, but employed in a more general and diffusive manner, with the view of imparting increased tone to the arterial system at large. This, I believe, may be accomplished by passing somewhat powerful single currents from the upper portion of the spinal cord through the uterus. The opportunities I have had of observing the action of galvanism in obstetric practice, induce me to think favourably of it in these cases, and some investigations commenced with the view of determining its power in arresting arterial hæmorrhage support this opinion: whilst it must not be forgotten, that several cases have been published in which uterine hæmorrhage has been thus speedily arrested. I will only add, that if my view of the source of hæmorrhage in cases of partial separation of the placenta is confirmed, it will prove a most valuable auxiliary in the treatment of placenta prævia; simultaneously tending to the arrest of hæmorrhage, and the dilatation of the uterus.

Chester Place, Hyde Park Gardens, Dec. 1853.

BRIEF CONSIDERATION OF MR. GAMGEE'S EXPERIMENTAL INQUIRY INTO THE EFFECTS OF INJECTING PUS INTO THE VEINS OF ANIMALS.

By HENRY LEE, Esq., F.R.C.S., Surgeon to the Lock Hospital, Assistant-Surgeon to King's College Hospital, etc.

IN THE ASSOCIATION JOURNAL for December 9th, Mr. GAMGEE has entered into a critical inquiry of the most recent opinions concerning the local effects of injecting pus into veins; and has entered at length into a consideration of my experiments upon the subject, which, he has done me the honour to say, "were, ever since their announcement, regarded as marking an era in the progress of knowledge of purulent infection."

The limits necessarily assigned to a communication to a medical journal forbid even a passing consideration of the whole subject; but Mr. Gamgee's experiments and observations afford some particular points well worthy of attention.

With regard to the principles themselves, they have been fairly stated to the profession, and have been reprinted and adopted in some of the most widely circulated surgical works in the English language. They must stand or fall by the test of public experience; but I cannot for a moment allow (as appears to be inferred by Mr. Gamgee) that the conclusions arrived at depend upon the accuracy of any one set of experiments.

Already have the descriptions of *subacute* and *acute phlebitis* given way to the descriptions of the local effects of inflammation of veins, and that general contamination of the blood to which the name *pyohemia* has been given: affections essentially distinct in their nature, but which may nevertheless frequently co-exist in the same case. As an instance of the truth of these remarks, I may refer to the differences observable between the chapter on Injuries and Diseases of the Veins, in the fifth edition of Dr. Druitt's excellent *Manual of Surgery*, published in 1851, and that in the sixth edition, which has just appeared.

With these observations, then, I must dismiss the general subject, and confine myself to the particular points mentioned in Mr. Gamgee's interesting inquiry.

The first sentence selected by Mr. Gamgee for especial criticism, and twice published for that purpose, is as follows:—"The simple experiment of mixing some pus with healthy recently drawn blood will at once show that such a combination cannot circulate in the living body. It will be found that the blood coagulates round the globules of pus, and forms a solid mass, which will adhere to the first surface with which it comes in contact."

It must be evident that, in this sentence, the relative "which" refers to its antecedent "solid mass", and not to the globules of pus; and it would be therefore most unfair to draw from it the additional conclusion, that no time was occupied in forming the solid mass, or that pus could, under no circumstances, be made to pass along the blood-vessels. If such an inference could have been drawn from a single sentence, it might surely have been corrected by other statements in the same work (*On Phlebitis*, etc.). Thus, at page 43, I write, that the experiments show that pus has a tendency to coagulate the blood; and that, from this cause, "its progress is arrested in some part of the circulating system"; and at page 24 I state that, "where purulent or other fluids have been directly injected into the blood, the examination of the blood or of the vessels will by no means indicate the presence of foreign matter, nor will inflammation of the vein through which the fluid has passed be by any means invariably produced." Finally, I have myself detailed four cases in the work referred to, in which pus was injected into the veins without producing any characteristic local morbid appearances. It appears, therefore, strange to me, that Mr. Gamgee should have inferred from my writings that I was of opinion that pus could never be made to pass into the circulation, and that he should have endeavoured to prove, in supposed opposi-

tion to my experiments, that "the circulation of pus with the blood is perfectly possible".

"To argue, as Mr. Lee does," continues Mr. Gamgee, "from the fact that, out of the body, blood coagulates round pus, therefore such a combination cannot circulate in the living body, is about as warrantable as it would be to predicate from the observation, that pure blood coagulates in a basin, it therefore cannot remain fluid in the ventricles of the heart."

With this criticism, though somewhat complicated, and manifestly inappropriate, as applied to a peculiarity in the mode of coagulation, I have, on the whole, not much fault to find, since Mr. Gamgee has himself furnished the evidence that vitiated blood, to which alone my experiments referred, will not always remain fluid in the ventricles of the living heart.

"A mixture of two drachms and a scruple of good pus, diluted with an equal quantity of tepid water, was injected", says Mr. Gamgee, "into the right jugular vein. I had no sooner done this, and transfixed the lips of the orifice with a pin, than the horse began to heave at the flanks, after which he staggered a few moments, and fell; when down, he breathed laboriously thirty-eight times in the minute, and, with scarcely a struggle, and not more than two minutes' delay, expired. . . The jugular vein and the right cavities of the heart were filled with dark coloured currant jelly-like clotted blood. . . From the manner the experiment was conducted, the introduction of air into the vein was impossible. On examining the blood from the right side of the heart, I discovered on it a very large number of corpuscles, measuring, on an average, one two-thousandth of an inch in diameter, and having nuclei not distinguishable from those of pus-cells. So numerous were they, that it was impossible to count them."

As the horse has only one jugular vein on each side, the blood returns to the heart through it, when unobstructed, with something like the same velocity that it passes from the heart through the carotid artery: a period of four or five seconds is the utmost time that the blood would, in the ordinary course of the circulation, take to pass through the heart from the jugular vein; yet, in Mr. Gamgee's experiment, the pus is found mixed with the clotted blood in the heart, after an interval of two minutes, without reckoning the time consumed in completing the experiments, or the interval during which the circulation may have gone on after apparent death. By what power, then, I ask, were these pus-globules detained in the heart? and what was the cause of the sudden death which occurred in this case?

This experiment of Mr. Gamgee's is the more interesting, as it coincides exactly with an experiment recorded in a very able and interesting paper by Dr. Mackenzie, in the last volume of the *Medico-Chirurgical Transactions*. At page 200, Dr. Mackenzie states: "The femoral vein of a dog was exposed on the 15th of June, 1852, and half an ounce of pus, slightly diluted with water, was slowly injected into it towards the heart. In rather more than a minute, the dog seemed distressed; the abdominal and respiratory muscles became convulsed; and respiration ceased within two or three minutes. On making a *post mortem* examination shortly afterwards, the vena cava and the abdominal and thoracic veins were found generally turgid with blood. On opening the right iliac vein, a stream of dark coloured fluid blood poured out; and, on continuing the division of the veins upwards, the blood was still found to be fluid, with the exception of two or three small coagula, which were found about the middle of the cava. The right auricle contained a thin black coagulum, and small fibrinous coagula were scattered over and between the columnæ carnea of the right ventricle, which contained a minute yellowish looking matter, closely resembling the pus which had been injected."

A third case, in which the injection of a putrid fluid produced analogous symptoms, is detailed at length in the *Medical Times* of the 3rd instant.

What is it, I again ask, that produces the sudden and alarming symptoms in such cases? There is no animal

poison known which is so sudden in its operation ; and that pus, simply as such, produces no such symptoms, we have abundant proof from those cases in which it has passed without obstruction in the course of the circulation.

In a Report of a Committee of the Edinburgh Physiological Society of the 9th of January, 1853, upon some experiments undertaken at the instigation of Professor Bennett, it is stated, that fresh and healthy pus was slowly injected towards the heart into the jugular vein of a donkey. A slight obstruction was at first perceived, and the vein above the ligature could be seen to be somewhat swollen. This swelling, on being felt, was very soft, and, on pressing the vein from below upward, the mixed blood and pus was readily pushed before the finger. When all obstruction to the passage of pus from the syringe was removed, the syringe was again filled, and another ounce of pus was injected, without occasioning any further local effects. The animal was then allowed to get up, and exhibited no change in its normal condition whatever. The same was the subject of a second experiment, a fortnight later, having been perfectly well in the interval. Six inches of the jugular vein were now exposed, and an ounce of perfectly healthy pus was then slowly injected downwards towards the heart. Another syringe full of pus was then injected. The animal presented no unusual symptom whatever during the next four days.

To what, then, are to be attributed the sudden and fatal effects observed in Mr. Gamgee's and in Dr. Mackenzie's cases? I answer, to the coagulation of the blood in the heart. It is to this that are to be ascribed the sudden and fatal results in the cases which these gentlemen have recorded; and to the absence of any such result, that the corresponding absence of symptoms must be assigned in the last mentioned experiments.

Thus, I conceive that, while it is fully demonstrated that, in certain cases, pus may pass into the circulation without producing any very manifest inconvenience, that, in others, it will produce coagulation of the blood in the lining vessels, and a train of consequent symptoms which will vary according to the locality in which such stagnation has taken place. What the circumstances are which, in one case, will determine this effect, and in another not, will form the subject of a separate inquiry. For the present, I must content myself with having shown, as I believe, from independent evidence derived from experiments undertaken to illustrate other and different views, that the doctrine which I first published in 1849 is not devoid of foundation; and that the propositions which I then endeavoured to establish,—namely, that pus and some other morbid fluids, when mixed with the blood, have a tendency to produce its coagulation, and that this tendency is often more quickly manifested in the body than out of it,—have been fully demonstrated.

15 Dover Street, Piccadilly, Dec. 13th, 1853.

DESCRIPTION OF A NEW BEDSTEAD FOR DIRTY INSANE PERSONS.

By JAMES G. DAVEY, M.D.

[Read before the Anniversary Meeting of the Provincial Medical and Surgical Association, August 11th, 1853.]

Among the insane there are, and always must be, even in the best regulated of asylums, and with the greatest care and attention, a considerable number whose mental existence is reduced to so low an ebb, that the calls of nature are either not heeded, or are kept in abeyance by an inordinate cerebral excitement, or by some absorbing and abnormal impulse, which involves the volition of the party affected in disorder and irregularity (*mania*). These constitute what in asylum parlance are called *dirty patients*; and, for their management and accommodation, various plans have, at different times, been suggested. In the olden time, this class of patients was very summarily dealt with. A little loose straw, and that not over clean, was

thrown into the corner of a damp and dirty cell; and the poor lunatic was fortunate indeed to have this exchanged when it was needed. At a less distant period, the straw was put into a coarse kind of sacking. After the lapse of time, however, both the loose straw and the coarse straw mattresses were abandoned, and their place was supplied by the common *stretcher*. This consists only of a stout piece of canvas extended over a framework of wood, of the length and breadth of the *crib*, and into which it is received. This arrangement is not unattended with much danger, inasmuch as violently disposed persons commonly remove the stretcher, and use it as a weapon of offence; or not infrequently break it into pieces, and do more or less mischief in and about the dormitory. To meet these grave objections, various ingenious plans are devised to fasten or lock the stretcher to the crib or bedstead.

Two objections are made, and very properly, to these stretchers: one is, that the canvas, if sufficiently strong, is not porous enough to allow the urine to escape; it is, therefore, retained more or less about the person of the patient, and risk is thereby incurred of sores: the other is the time and labour demanded, not only to wash and dry the stretcher for further use, but to carry it to and from the laundry and the wards.

The first objection has been met by piercing holes in the canvas, similar to those which tailors are in the habit of making on the back parts of waistcoats, to enable us, in physiological phrase, to adapt the containing to the contained parts. The due escape of the animal fluids, however, leaves yet the second objection untouched; and to remove this very serious business, in a lunatic asylum containing any number of patients, is the especial purpose of the *cane* bedstead, to which I would here call attention.

By referring to the drawing, it is seen that the whole depth of the *crib* is divided into two parts, an under and an upper, by the cane flap or partition which intersects it in its whole length and breadth. On the one side of the interior of the crib, the cane flap or shifting bottom is held on hinges; and, on the other side, it fastens with a kind of spring lock, which is opened from the outer side or exterior by a key of a peculiar construction. The specific value of the above arrangement consists in the employment of *cane* in the stead of canvas. This material, from the great abundance of silica which it contains, mixed with vegetable matter, offers a non-absorbing surface to the urine; and all the washing, therefore, which it requires may be performed by a damp piece of flannel, which may be used daily by the ward-attendants themselves in the dormitory, as the crib stands, with scarcely any trouble. (Figs. 1 and 3.)

Fig. 1.

Fig 2.

Fig. 1 represents the bedstead with the cane flap put down, and in position for use. On the cane flap the bedding is placed. N.B. The finer the canework the better.
Fig. 2 represents the bedstead with the canvas expanded by the rods placed on either side; and which, passing from the head to the foot-board, preserve the same in situ.

The lead which lines the interior and bottom of the crib must of course be kept perfectly clean, as is done under any other circumstances. The addition of the ordinary drawer, containing a common chamber utensil, either of earthenware or gutta percha, would together constitute an admirable piece of furniture for the lunatic asylum.

Fig. 3.

Fig. 4.

Fig. 3. In this drawing the cane flap is raised on its hinges; on one side is shown the bolt withdrawn, by means of which the flap is secured by an appropriate key, in its right place, when in use.

Fig. 4. In this drawing the canvas, with the rods, by means of which it is extended, is raised, in order to show its relation to the contiguous parts. Like the cane flap, the canvas divides the depth of the bedstead into two unequal parts.

There is another form of bedstead, which is doubtless greatly to be preferred to the canvas stretcher above referred to; but I think myself it is inferior to the cane bedstead here submitted for inspection. Its peculiarity consists in a contrivance which allows of the ready separation of the canvas from the framework to which it is attached in the crib; the frame itself being a fixture, or a part of the crib. The canvas, in this instance, may be described as a common kind of sack, equally open at either end. This is slipped on or off certain iron rods, which secure it, as required; and these are attached by a joint on each side to the upper and interior part or head of the crib, and are continued to the lower and interior or foot of the same. These rods are perfectly close to its sides, where, at points corresponding to the said joints superiorly, they fall into grooves on the interior of the foot-board, which proceed from the centre to the sides of the crib. The canvas or sacking, being slid on the iron rods, is readily extended across the bedstead; and on it of course the patient lies. The whole is secured by two common screws, which are reached from the outer side and foot of the bedstead. A piece of canvas, six feet by two, is more conveniently carried to and from the laundry and the wards, and much more easily washed and dried, than the frame or stretcher could possibly be. (Figs. 2 and 4.)

I am bound to acknowledge the assistance given to me, in matters of detail, in the contrivance of these two cribs or bedsteads, by Mr. Holman, the engineer of the County Asylum at Colney Hatch, whose mechanical ingenuity is of no ordinary kind.

Care should be taken not to fix either the *cane flap* or the *iron rods* too near the top of the crib, else the patient will lose the security the crib affords him. Those among the insane who are *hopelessly* of dirty habits, are, as a rule, more or less helpless and imbecile or demented. I may add, that dirty patients, in asylums for the insane, are not infrequently put to sleep on mattresses covered with oiled silk or India-rubber sheeting; and, in the centre of each mattress, and of its coverlid, there is commonly a hole through which the animal fluids *may* pass away. But not only do these *not* answer the purpose intended, but the urine is retained in parts about the surface, and so keeps

the posteriors of the patient saturated with moisture: moreover, their expense is very great.

In conclusion, I may remark, that both the kinds of crib are in use at the Colney Hatch Asylum, and, I am told, at the Asylum at Hanwell. I am assured, too, that, at the former institution, they continue to be highly approved.

Northwoods, Bristol, Aug. 8th, 1853.

BIBLIOGRAPHICAL NOTICES.

A TEXT-BOOK OF PHYSIOLOGY. By Dr. G. VALENTIN, Professor of Physiology in the University of Berne. Translated and Edited from the Third German Edition, by WILLIAM BRINTON, M.D. Part II. London: 1853.

WE have already noticed in favourable terms the First Part of the translation of VALENTIN'S PHYSIOLOGY by Dr. BRINTON. The whole work is now before us, and we can conscientiously speak in its praise. It is described by Dr. Brinton as an abridgement, by Dr. Valentin, of the last edition of his larger systematic treatise, the "Lehrbuch der Physiologie."

The book is divided into nineteen chapters, which treat successively of Organization and Life, of Organic and Animal Functions, of the Physical and Chemical Properties of the Body, of Digestion, Absorption, Circulation, Respiration, Evaporation, and Secretion; of the Vascular Glands, by which term the author designates the spleen, the suprarenal capsules, the thyroid and the thymus glands; of Nutrition, Animal Heat, Locomotion, and the Voice; of the Functions of the Senses, of Innervation; and lastly, of Generation and Development.

To offer any detailed opinion upon the merits of Professor Valentin as a physiologist may be deemed superfluous, when we consider the high reputation which he already enjoys upon the Continent. We shall therefore only remark that he possesses those qualities of mind, natural and acquired, which render him a trustworthy authority in matters of science. He is fully acquainted with the literature of physiology and with the collateral sciences on which its principles are founded; and he has moreover enriched his pages with many ingenious experiments devised and executed by himself. He is a calm and dispassionate critic of the many disputed points in physiology; and his own views are always based upon extensive knowledge and correct reasoning.

We do not by any means affirm that, as a Treatise on Physiology, the present work is decidedly superior to other books upon the same subject, especially the works of Müller and of Carpenter; but as this department of science is one which is continually changing its features, in consequence of recent discoveries in histology and chemistry, of the different aspects in which the same truths may be presented to different minds, and of the institution of new experiments, a work on this subject coming from a philosophic writer and experimentalist is always acceptable; and Valentin's present contribution to physiology is one of the highest order. Modern physiology is like a kaleidoscope, in which the most dissimilar objects appear to be heterogeneously jumbled together before the ordinary observer; but it is the province of intellect to collect and arrange the scattered elements, to reduce them to system, and to unite them into a coherent and harmonious scheme. This has been done in Valentin's Text-Book, which is therefore to be recommended as a safe and useful guide to the student and the practitioner.

To Dr. Brinton a considerable meed of praise is likewise due; the translation is carefully and neatly performed, and the notes appended to the text, although few, are well-timed and judicious.

There are no fewer than five hundred illustrations interspersed throughout the volume, on wood, copper, and stone, and some of these are of the most elaborate character, and are executed with great accuracy.

We regret that our limits do not allow us to give an abstract of the whole work, and it would be unjust to the author and the translator to give isolated extracts from its pages. The latter course would be the more unfair, as the aim of the author has apparently been to arrange his materials in logical succession; and the selection of random passages could no more give an idea of the composition of the book, than the exhibition of some loose bricks could afford a specimen of the architecture of a house.

DRUGGISTS' HAND-BOOK OF PRACTICAL RECEIPTS: A Manual for the Chemist and Medical Practitioner, comprising the London Pharmacopœia in English, etc. By THOMAS F. BRANSTON. 12mo. pp. 256. Liverpool: 1853.

This work is likely to prove useful to those for whose use it is intended.

PERISCOPIC REVIEW.

SURGERY.

DISLOCATIONS OF THE ANKLE BELOW THE ASTRAGALUS.

Dr. PAUL BROCA has contributed a memoir on this subject to the third volume of the *Mémoires de la Société de Chirurgie de Paris*. He enters at great length into the history of what he terms *sub-astragalian* dislocations. The displacements of bone which occur in the tarsal region are so numerous and varied, that M. Broca thinks it necessary to establish subdivisions and a methodical nomenclature. He divides them into three classes; but before proceeding to describe them, he gives an anatomical view of the relations of the astragalus to other bones.

The astragalus may be described as the key of the ingenious mechanism of the ankle; it is the bone which receives directly the weight of the body and transmits it to the other bones of the tarsus. Notwithstanding its small size, it articulates with four different bones, and its numerous articular surfaces take part in all the movements of this complicated region. Three supposed articulations are grouped, as it were, around the astragalus; the first is the tibio-tarsal, which is almost the exclusive seat of flexion and extension; the second is the *sub-astragalian*, under which term the author comprises, not only the two astragalo-calcæan junctions, but also the astragalo-scaphoid connexion. In the movements of this triple articulation, the astragalus, fixed to the bones of the leg, remains immovable, and the rest of the tarsus moves below it, so as to carry the point of the foot inwards or outwards, which constitutes adduction and abduction. The third articulation is the medio-tarsal. The astragalus and the calcaneum, constituting a solid mass, furnish a double articular surface on which the anterior range of the tarsus rests. The movements of flexion and extension are here very obscure, those of adduction and abduction hardly exist; but this articulation is the principal seat of those movements of torsion, which elevate one of the edges of the foot by depressing the other. The three articulations of the ankle may be moved together or singly; and they may therefore be dislocated separately or all at once.

M. Broca divides the dislocations into four groups: 1. The *tibio-tarsal* luxations, of which he does not here treat; 2. The *subastragalian* luxations, in which the astragalus preserves its relations with the bones of the leg, while the rest of the foot is carried in a variable direction; 3. The *medio-tarsal* luxations, in which the posterior range of the tarsus preserves its relation with the leg, while the anterior range is displaced altogether or in part; 4. The *luxations of the astragalus properly so called*, in which this bone, by a complex movement and as a result of extreme violence, is expelled from the cavity which it occupies without the other bones of the foot losing their mutual relations. This classification, says the author, is not an imaginary one, but is founded on real distinctions. The memoir is divided into two parts, one of which treats of sub-astragalian, and the other of medio-tarsal luxations.

The luxation of the os calcis has very rarely been observed; and, even after examining the recorded cases, M. Broca is induced to doubt the reality of this accident. Of the existence of

dislocations below the astragalus there can be no doubt; and the case of Mr. Carmichael is related, in which it is shown that that distinguished surgeon, meeting with an accident on horse-back, dislocated the os calcis backwards, the astragalus retaining its position. This kind of dislocation is distinguished from the luxation of the foot backwards, first, by the presence, on the dorsum of the foot and in front of the bones of the leg, of a round projection formed by the head of the astragalus; and secondly, by the absence of the tumour which is formed by the pulley of the astragalus behind the bones of the leg, when the whole of the foot is displaced. The lateral luxations of the subastragalian articulations are less rare than the luxation backwards; and the author has collected nineteen cases of this displacement. The signs of the luxation outwards are the following: the foot is in general carried in an abduction more or less considerable, or it may even take an entirely transverse direction; the external edge of the foot is almost always elevated, and the internal edge rests on the ground. When there is a wound, it is situated on the inner edge of the foot, below or in front of the internal malleolus, and allows the head of the astragalus to project; the tendon of the tibialis posticus is pushed backwards or torn; the posterior tibial artery is distended or torn. The following are the signs of the luxation inwards:—the foot is carried in the direction of adduction, its internal edge is more elevated than in the normal condition, which produces to a certain extent the form of talipes varus. When there is a wound, it is situated on the outer side of the foot, below or in front of the external malleolus. The tendons of the extensor communis are pushed back over the inner side of the head of the astragalus, which rests in general upon the dorsal surface of the cuboido-scaphoid articulation. The two most essential signs of these luxations are derived from the position of the astragalus in relation to the malleoli, and from the state of the movements of the foot. Whenever the head of the astragalus has preserved its normal relations to the bones of the leg, which fact may be always easily ascertained, the existence of a subastragalian dislocation is certain. The integrity of the tibio-tarsal articulation gives an important functional sign; for the movements of extension and flexion of the ankle, which are abolished in the tibio-tarsal luxations, and in the total luxations of the astragalus, are preserved in the subastragalian luxations.

The indications of treatment must be deduced from the foregoing considerations. When there is no wound, the reduction must be attempted as soon as possible. The extending forces must be applied at once to the dorsum of the foot and the projection of the heel, and must be exerted in a direction parallel to the axis of the leg. Counter-extension is to be made upon the leg, which ought to be flexed upon the thigh, in order to relax the gastrocnemii muscles. If manual force should fail, recourse must be had to pulleys. But it may happen that the reduction is impossible; and in such cases some authors have advised the use of incisions to relieve obstacles; but M. Broca thinks that such treatment is inadvisable. When there is a wound the case is more serious, and some surgeons have recommended amputation; but this can only be adopted in rare cases. The reduction of the luxation must be attempted, but it unfortunately fails more frequently than in luxations uncomplicated with a wound. The division of the soft parts, or the section of certain tendons may facilitate the replacement of the bones; but in spite of this, the luxation often remains irreducible, and it becomes necessary to extract the astragalus. The removal of this bone permits the straightening of the foot; and of eight patients who have undergone the operation, six have recovered. Removal of the astragalus is a less severe operation than amputation of the leg, and it presents the advantage of preserving the functions of the limb.

The latter part of M. Broca's memoir is devoted to the consideration of the *medio-tarsal* luxations, by which term are denoted the displacements which occur between the first and the second row of the tarsal bones; namely, in the articulation called Chopart's. The luxation will be *total* if the scaphoid and the cuboid bone are displaced simultaneously; and *partial* if one only of these bones be luxated. The conclusion at which the author arrives, is that nothing authorises us to admit the reality of the total medio-tarsal luxation, and that the dislocations of the scaphoid bone which have been described by some surgeons, are really subastragalian luxations. M. Broca criticises very ably the cases of astragalo-scaphoid luxations described by Boyer, Roux, Astley Cooper, and others, and considers that they are all incorrectly designated, and that by a more accurate diagnosis of these displacements remedial measures might be more successfully employed.

ON THE TREATMENT OF ERECTILE TUMOURS BY A NEW METHOD OF LIGATURE.

In the third volume of the *Memoires de la Société de Chirurgie* of Paris, there is a paper on the Treatment of Erectile Tumours, by M. RIGAL. After reviewing the different methods hitherto employed in the treatment of these affections, M. Rigal recommends the ligature as the preferable proceeding, employed in a manner peculiar to himself. It consists in using a multiple ligature, the loops of which are tied beneath strong pins, and thus strangle the tumour without running the risk of allowing the least part of it to escape. The following is the plan described by M. Rigal, in one of his recorded cases. A sewing needle of sufficient strength was carried across the tumour and beneath it, drawing the two ends of a thread through the puncture. A second needle was passed in the same manner below the tumour; their passage thus divided the tumour into three parts of about equal size. Each of the threads was then cut off close to the needles, and thus there were two ligatures free in each of the passages. Then a small and rather strong curved needle was plunged below the upper extremity of the tumour, and was made to pass out on the opposite side. The two extremities of one of the threads were then firmly tied below the needle; the same proceeding was taken at the other end of the tumour. The middle part was perforated by another needle, and one of the upper, and one of the lower threads were tied together beneath it, thus completely strangulating the middle portion of the tumour. The interlacement of the threads, although easily demonstrated by diagrams, is however too complicated for verbal description; but it is sufficient to state, that when the threads are all drawn tightly together, the result was the separation of the erectile tumour from the surrounding parts. The ends of the pins were removed by the cutting pliers. The tumour daily acquired a deeper and deeper brownish tint; it hardened as it became dry. Soon afterwards, the furrow marking the line of strangulation began to ulcerate, pouring out a few drops of well conditioned pus; and on the eighth day, the erectile tissue dropped off spontaneously, bringing away the pins and the loops of thread. Although the number of the ligatures and of the pins requires to be varied according to the size and the situation of the tumour, the principles of the operation remain always the same; and no deviation was adopted in any of the operations of M. Rigal, who illustrates his observations by the record of seventeen cases, all of which were successful.

The conclusions arrived at by M. Rigal are the following; namely, that the ligature above described, and which M. Rigal calls the *ligature à chaîne enchevillée*, constitutes a new method for the removal of erectile tumours; that it is applicable not only to pedunculated tumours, but also to morbid productions reposing upon broad bases; that it may be employed upon all the regions of the face and trunk; that it prevents the hemorrhage which accompanies or immediately follows a sanguinary operation, and that which may probably result from the falling of mortified tumours; that its efficacy, its safety, and the little influence which it exercises upon the economy, appear to depend directly upon the energy of the constriction, on the instantaneous isolation, and the immediate death of the parts comprised within the double enclosure of its knots; that the scars which result are firm, moveable, and of a remarkable smoothness, and are obtained by the aid of very simple dressings; that the operation is rapidly performed, and that the presence of the pins causes no pain, even in children; that this kind of ligature permits the operator to spare a more or less considerable portion of a moveable structure, such as the lips and the eyelids, even when two thirds of the thickness of these organs have been involved; and that, although it may not be adapted for every case, it will yet be found the most appropriate treatment in a great many instances.

RESEARCHES ON THE INCOMPLETE LUXATION OF THE TIBIA FORWARD.

In the same volume from which we have taken the above, a paper on this subject is communicated by M. DÉSORMEAUX, illustrated by a case which came under his notice at the hospital Bon Secours. The patient became accidentally entangled in some machinery, by which accident direct violence was applied to the region of the knee, and a partial dislocation of the knee forward was the result. The luxation was reduced, but the patient subsequently died of consecutive disease. On examining the knee-joint, it was found that the articular capsule was uninjured, but it contained a little serosity mixed with blood; the ligamentum patellæ, the lateral ligaments, and the posterior and semilunar ligaments were healthy, and the crucial ligaments

were infiltrated with blood. M. Désormaux considers the principal symptoms of this luxation, to be the projection of the tibia forward, permitting the anterior part of the glenoid cavities of this bone to be distinguished by the touch; the projection of the condyles of the femur in the popliteal space, and the consequent increase of the antero-posterior diameter of the articulation, the absence of real shortening, and the position of the patella, the anterior surface of which looks forward and upwards, and presents remarkable depressions at its sides. The best method of reduction consists in the flexion of the limb, combined with a slight extension.

MATERIA MEDICA, PHARMACY, AND THERAPEUTICS.

PREPARATION OF PERCHLORIDE OF IRON.

In the *Bulletin Générale de Thérapeutique* for May 15th, and the *Lancet* for June 18th, is given M. BURIN DUBUISSON'S formula for preparing the perchloride of iron.

"Take of sulphate of iron of commerce (emerald colour), two pounds; water, six pounds; pure iron filings, the fifth part of a pound; sulphuric acid, half an ounce: put the whole into an enamelled cast-iron vessel, and leave the latter upon the sand-bath until gas is no longer given off; filter, add to the fluid half a pound of liquid hydro-sulphuric acid, and allow to rest for twelve hours. Put, after that time, the solution upon the fire, boil for half an hour, and filter. To the filtered liquid add six ounces and a half of pure concentrated sulphuric acid; and place the mixture into an enamelled cast-iron vessel, which should be but half filled. Boil, and add in small quantities, pure nitric acid, until it causes no longer the escape of red fumes. Remove the vessel from the fire, add to the fluid twenty-five or thirty times its weight of cold water, and the whole of the iron will be precipitated in the state of peroxide by the addition of a slight excess of ammonia. Wash the precipitate by decantation with pure water a great many times, and dry it in the air by spreading it in thin layers upon linen.

"This dry and pulverised oxide is then calcined to redness in a large and shallow iron vessel, so that the temperature may not rise too high. This is the martial saffron of the shops, which is, in fact, pure peroxide of iron when prepared as above.

"The perchloride of iron is then obtained in the following manner:—Take of the peroxide of iron, resulting from the process just described, six ounces and a half; pure and white hydrochloric acid, two pounds; mix, and allow the action to go on without fire for five or six hours; then put the vessel on a water-bath, and boil until the almost complete solution of the oxide is obtained; this should be done in a porcelain capsule, weighed beforehand. The liquid is decanted to separate the undissolved oxide, and the former is carefully evaporated upon the water-bath, constantly stirring, to the consistence of thick syrup, which is then weighed. Half this weight of distilled water is then added, the heat is kept up for a few moments, and the whole is thrown on the filter. The capsule and the filter should now be washed with a quantity of water equal to that used in the last place, and to the first fluid obtained, as much of the second is added to get a mixture of the density of from 43.5 to 44 degrees.

"By proceeding in this manner, a very limpid fluid is obtained, with a slight acid reaction, but perfectly pure, having reached the maximum of saturation, and always identical. It may be kept without any of the salt being thrown down, provided the bottle be well stoppered; the colour is dark-brown when the liquid is looked at in full, and of a greenish-gold colour when held to the light, or seen in a thin stratum. Five or six drops of this fluid, mixed with the white of an egg diluted with six drachms of water, are sufficient to coagulate the whole into a mass in the space of fifteen seconds. This mass firmly adheres to the bottom of the glass when the latter is turned up, and takes a pretty long time before it slowly drops, when the watery parts begin to run off, as the serum separates from coagulated blood."

SULPHATE OF ZINC AS AN ANTISEPTIC.

M. FALCONET recommends a solution of sulphate of zinc for preserving animal substances subject to early decomposition, such as the brain and intestines; he states that they thus retain their characters unaltered, by contraction or otherwise, and that the steel instruments employed in operating on the substances thus injected are not injured by the liquid employed.

EDITOR'S LETTER BOX.

TRANSACTIONS, OR A WEEKLY JOURNAL?

LETTER FROM T. HERBERT BARKER, M.D., TO THE EDITOR.

SIR,—Many readers of the JOURNAL must have noticed a hint that the old members of the ASSOCIATION felt regret that the volume of *Transactions* should have been discontinued. I cannot join in such regret; and when you are informed that, at Oxford, I was one of the minority in the division on the Journal question, you will give me credit for sincerity in the statement of my present opinions. At one time I was fully satisfied with the *Transactions* and a fortnightly Journal; but it now appears to me that the value of the Journal, in every point of view—not only in its weekly instead of its fortnightly issue, but also in its literary, scientific, and medical character,—has so much increased, as to render the publication of *Transactions* quite superfluous. It cannot be doubted that a volume of *Transactions*, as well as the weekly Journal, would be very acceptable to the members; but it is unreasonable to ask both for a guinea. To my mind, the wonder is, how we can get so much paper and printing, not to speak of literary talent, for so small a sum. But it is so necessary that a volume of *Transactions* should be published, as well as a weekly Journal? for the latter affords to the longer papers, essays, addresses, etc., a medium as eligible as the former. Probably some would be inclined to state, that the essays, addresses, etc., would be forgotten in the Journal, and can only be kept from oblivion in a volume of *Transactions*; but, in truth, is not a volume of the Journal as likely to be reached from the book-shelf as a volume of the *Transactions*? It is true, that long essays would have to be inserted piecemeal (as is done, for example, with Mr. Ancell's papers); but then the integrity of papers so divided is not thereby destroyed; and the permanent value of our annual volume is much increased by its containing elaborate articles.

It appears to me that the whole strength of the ASSOCIATION should be thrown into the Journal. It is the most tangible *quid pro quo* that I know of in any society. If other associations—such as the British Association for the Advancement of Science, or the Royal Agricultural Society—had the materials with which they could commence and sustain a weekly journal for their members, instead of the *Transactions* (frequently of very spare habit, it must be confessed) which they issue, it would lead to a much more successful state of things. It is often a source of regret and complaint, that a better return for the subscription is not made in these societies. In our own Association, for our guinea subscription, we have, in addition to the advantages belonging to simple membership—which must not be too lightly estimated—a weekly Journal, which, in many hundreds of cases, saves the subscription to another periodical, which it could do very seldom if published fortnightly. The medical man requires a publication giving the medical intelligence of the week, in order to keep *au courant* with the progress of medical science.

It is not necessary that any invidious comparisons should be made between the past and present editorial conduct of the Journal, or between our own ASSOCIATION JOURNAL and other medical periodicals. For one, I will merely add, that, although I voted at Oxford against any change, I would now decidedly prefer the present to the former regime; and I am greatly mistaken if the vast majority of members have not the same preference. If so, let us all combine cordially and perseveringly to sustain and increase the value of the Journal; let us try to double the number of members of the Association, by offering, as we can now do, the inducement of a TRULY VALUABLE WEEKLY JOURNAL; and we shall thus do good service to the profession and to the community. Very valuable materials have during the current year been laid before the members—materials well worth binding and preserving. There has been a good combination of the advantages of promptness of publication with solidity and permanence of value; and the current topics of the profession have been judiciously brought before our view, and have occasionally given rise to instructive and free discussions among the members. In fact, I submit it to the readers, if they have not had a goodly allowance of the truly solid and useful, interspersed with a fair supply of lighter articles.

One subject of very great congratulation is to be found in the fact that many of the foremost of our metropolitan brethren have cordially joined us, and have given a powerful support to our Journal by enriching its pages with their own contributions.

It is my belief that, if the general and individual advantages which flow to the profession from having a good weekly Journal, as a recognised organ, were generally known and appreciated as they ought to be, the number of members of our noble Association would soon be more than doubled. You will, therefore, much oblige me by inserting these remarks in an early number.

I am, etc.,

T. HERBERT BARKER.

Bedford, December 19th, 1863.

MEDICAL ETHICS.

LETTER FROM C. RADCLIFFE HALL, ESQ., TO THE EDITOR.

SIR,—The subject of medical ethics is occupying the attention of the ASSOCIATION, and with so energetic a leader as Mr. Michael, no doubt the committee will produce all that is possible in the form of a code of ethical laws. But feeling less sanguine than many as to the extensive utility of such a code, when we have obtained it, I would just glance at the object we seek, and at the nature of the means for gaining it.

Our object is, I presume, to lessen the frequency of what we call unprofessional conduct either towards the public, or towards each other. Now, if the question of unprofessional conduct were in most instances distinctly one of right and wrong, unquestionably a set of express laws would be as useful and as necessary as are the general laws of the realm. But there is no parallelism. The professional question at issue is far more commonly one of feeling and of gentlemanly propriety than of mere right and wrong. It is found to be impossible and quite unnecessary to reduce the behaviour of the more polished members of society to any express rules. You cannot codify good manners. All that ethics can teach us individually, is, "to do as we would be done by". To carry out this simple golden rule, is a matter of inherent principle, not of ethical laws. We probably, none of us, err from ignorance. In a given case, the "black sheep" knows full well how the golden rule would direct him. Why then does he err? Just like all other men, because he acts worse than he thinks. Will any code of ethical laws prevent this? Not unless it could comprise every form of deviation from strict professional behaviour. May it not rather—if it have any influence at all—lead the so disposed to say, in an equivocal case, "this is not forbidden in the code, therefore I may do it."

Again, in what appear to be unprofessional acts, so much depends upon the minute circumstances of the case, so much upon considerations known only to the parties immediately concerned, that none, save the most glaring departures from correct conduct, could with justice be brought under the power of ethical laws. Very different, therefore, in effect is the working of an ethical society from that of a mere *litera scripta* of ethics. A number of unbiassed gentlemen, having all the particulars of the case closely investigated and thoroughly discussed, will seldom fail to arrive at a correct judgment.

Dr. Percival, when practising at Manchester, wrote the classical work on medical ethics. The work was well digested and arranged, and elegantly written. Of our professional brethren in that important city, how many have ever read the "Code of Medical Ethics"? and how many ever refer to it in any case of a questionable nature! Some ten years since, Manchester established a Medico-Ethical Society. Of its utility and practical influence I have personal knowledge.

But it is replied, we cannot everywhere have a Medico-Ethical Society. I fear, also, we shall not everywhere have a printed code of ethics attended to. We must carry our ethics within our breast. What is required is, that every professional man be a professional gentleman. With the golden rule as our principle, a certain amount of delicacy of feeling and refinement of manners will suffice to lead us pleasantly and correctly through every dilemma in which the question of ethics arises. With these, the code will be little thought of; without these, the code will be little used.

The problem is—Given a professional man, to ensure his being a professional gentleman. Neither medical reform, nor a code of medical ethics, nor legislation of any kind can work it. The article must be of self-manufacture. Let us have the code when prepared, but meantime let each of us determine within himself never to do in the practice of his profession what is in itself wrong, nor even what may appear to be ungentlemanly. The phrase is vague, perhaps, but its very elasticity is an advantage, and we all know what it means. And if it should happen that we are not all ourselves gentlemen (the reader, of course, excepted), let us take care that the next generation of professional men shall be, by insisting on their undergoing such an extensive

and liberal preparatory education, as shall make it easier for them to be gentlemen than anything else.

Having small faith in the results of medical reform, and (judging from myself) believing that the only reform which will do us any good is self reform, and feeling no confidence in the usefulness of a code of ethics, further than as a general guide for Medico-Ethical Societies, I hazard these cursory remarks, because I believe the truth that self-guidance and not code-guidance must govern us, is in some danger of being overlooked in the ardour of our search after ethical laws.

I am, etc., C. RADCLIFFE HALL.

Torquay, Dec. 15th, 1858.

[Laws do not secure obedience; but their existence is nevertheless useful in all communities and societies, whether public or private. Medico-ethical laws are not expected to be more universally respected than other laws; but they are expected, at least, to be sufficient to keep the Association freer than it has been from charlatans and advertising empirics. Some of the scandals under which we labour are so palpable as to be grasped by laws perfectly simple and easily enforced. EDITOR.]

MEDICAL METEOROLOGY.

LETTER FROM GEORGE F. BURDER, M.D., TO THE EDITOR.

SIR,—Will you allow me a few words in justification of the remarks I made in a former letter upon the medico-meteorological tables published in the Journal?

Dr. Barker's statement, that he has failed to find in my letter any legitimate objection to the method adopted, or any suggestion of a sounder method in its place, would have come with greater force, if his subsequent remarks had not shown that he has altogether misconceived the purport of my letter. It would, indeed, be a "strange kind of logic", which should "prefer *weekly* rather than *daily*, or *twice daily* observations, because it is impracticable to make *hourly* observations"; but scarcely stranger than that Dr. Barker should be able to discover any such preference in my remarks. In reference to this point, it will be sufficient to refer such of your readers as feel any interest in the matter, to my previous letter; and meanwhile to suggest to your correspondent (if he will not consider it a "frivolous objection"), that what is worth answering, is commonly worth understanding.

Dr. Barker is manifestly in error, when he states that any plan embodying the substance of my suggestions has been adopted, and has failed. Or, if the statement be correct, and if it be true that no constant connexion is discoverable between the *weekly* prevalence of particular diseases and the *weekly* means of the various atmospheric elements, surely this should be an argument for relinquishing the inquiry altogether, rather than for rushing into a system, which, without promising the discovery of any additional truth, only multiplies the chances of error. But where, I would ask, are the records of any medico-meteorological observations, conducted with accuracy, on a sufficiently extensive scale, by competent observers, and afterwards worked out by persons accustomed to such inquiries? The Registrar-General's returns are doubtless of great value as far as they go; but, having reference to deaths alone, of necessity do not supply the desideratum here referred to.

There are so many diversified aspects under which questions of this class may be discussed, and so many sources of error against which it is necessary to guard, that, in writing upon the subject, it is difficult to avoid being led into a controversy tediously minute and technical. Yet there are one or two points to which I must request permission to refer.

The superiority of a plan laying stress upon the precise hour of the commencement of a disease, over one taking cognizance of longer periods of time, rests upon two assumptions; namely, first, that it is usually possible to ascertain the precise hour of seizure; and, secondly, that it is reasonable to look for the atmospheric cause (if there be any) in the indications of the meteorological instruments at that hour.

With regard to the *first* point, it will, I think, be admitted, that in the great majority of cases it is *not* possible to ascertain so exactly the period at which a disease commenced. Even in those cases in which the advent is (apparently) most sudden, it is common to find that there have been premonitory symptoms of a much less certain date. Moreover, the errors liable to arise from this source are, by their nature, not self-compensatory. If it seem "frivolous" to urge as an objection, that a disease alleged to have commenced at 3 P.M., may in reality have dated from noon, the frivolity must be laid to the charge of those who insist upon this precision as a main feature in their scheme.

The *second* assumption is, I venture to think, not more tenable than the first. If atmospheric influences do play a part in the generation of disease, it seems reasonable to suppose that this effect must be in some measure proportioned to the continuance of these influences. Changes of temperature, it is well known, are not fully felt within doors until many hours, or even some days, have elapsed; and as, probably, the great majority of persons pass a larger part of their time within doors than in the open air, and very many persons pass nearly the whole of their time within doors, is it not much more reasonable to look for a connexion between the mean temperature of a number of days taken together and the prevalence of diseases during that period, than to insist on the precise point at which the thermometer stood at the hour when each disease first showed itself by symptoms? Even in the case of barometric and other changes, which are felt simultaneously within doors and in the open air, is it not reasonable to suppose that a certain interval should be required for the development of the effects of such changes upon the human frame? And, hence, is it not more reasonable to expect the truth to come out by a comparison of weekly periods, than by a comparison of any number of isolated observations, even although readings of all the instruments may have been taken at the exact hour when each disease was supposed to commence? If cold have a tendency to induce bronchitis, and a thousand cases of this disease are under consideration with a view to determine the point, is it more likely that the truth will come out by a series of comparisons founded on the reading of the thermometer at the very hour when each attack was said to have commenced, or by a series of comparisons in which the cases are massed into weekly periods, and the mean temperature of each of these periods stated? If, again, a high temperature have a tendency to generate cholera, and cases are before us for analysis, is it not more reasonable to expect to bring out the connexion between the two by a comparison of weekly periods as before, than by a classification, in which each case would stand opposite to the reading of the thermometer at the hour of its occurrence? By the latter method, the inquiry is limited as much as possible to the *instantaneous* effects of temperature; by the former, its effects would be recognised whether they were more or less immediate.

Dr. Barker replies to one of my objections by saying, that, if I were "practically acquainted with meteorology", I should know that "barometric and thermometric changes are not ordinarily so sudden and abrupt, but that observations twice daily will give ample guidance for correct conclusions." This I take to mean either that the diurnal variations, being small, may be practically disregarded, or that the kind of change indicated by a comparison of the two observations, may be assumed continuous throughout the day. In either case, where is the advantage of the *hourly* method of recording diseases? If, for example, the atmospheric conditions to be placed against the occurrence of a disease at 8 P.M. are only those obtained by the readings of the instruments at 9 and 3, what medico-meteorological deduction can be drawn from a knowledge of the *hour* of its occurrence, over and above those which may be drawn from a knowledge of the *day* of its occurrence? In the case of the *thermometer*, it may perhaps be said that by the application of the established corrections for mean diurnal range, the temperature at the hour in question may be approximately determined; but to this case, I have only to apply the objections which have been already urged.

To the table which is put forward by Dr. Barker as a specimen of the method of observation required, I should have made no further allusion, if I had not been invited to do so. As it is, I need scarcely do more than refer your readers to the table itself, where, if they have not already examined it, they may be as puzzled as I was at finding that, out of 24 instances in which, by the ordinary construction of per centage tables, the *sums* should amount to 100, only 12 fulfil even approximately that requirement. Thus, of 100 cases of epistaxis, we are told that 50 occurred with ozone, and 25 with no ozone. Of 100 cases of pleurisy, we are told that 0.5 occurred with a west, and 1.4 with a north-west wind; no cases occurring when the wind was in other directions. The only explanation I could suggest for these discrepancies (and, I admit, a very far-fetched one) was, that the calculation included all the cases of epistaxis and of pleurisy that had occurred within a given time, and that, out of these, only 75 per cent. in the one case, and less than 2 per cent. in the other, had been observed in their connexion, respectively, with the presence of ozone, and with the direction of the wind. Even this solution, however, failed me as I read on, and found that, of 100 cases of epistaxis, 37 occurred with an

increase, and 74 with a decrease of barometer readings! that, out of 100 cases of toothache, 19 occurred with an increase of barometer readings, and 80 with a decrease! and, above all, when I came to the last line, and read that, out of 100 deaths from all causes, 76.2 occurred with a north-west wind, 52.3 with an east wind, 42.3 with a north-east wind, 36.0 with a west wind, 35.1 with a north wind, 25.5 with a south-east wind, 25.1 with a south wind, and 24.1 with a south-west wind!!

In conclusion, as Dr. Barker appears the less pleased with my previous remarks on the ground of their containing no positive suggestion of value, I may perhaps be permitted to observe, that the detection of an error, although a humbler, and commonly a thankless office, may nevertheless be as real a service to the cause of science, as the suggestion of an improvement. But I have no wish to exaggerate the importance of my suggestions. If they are of any value, they will speak for themselves; and I should be sorry to overstep the bounds of diffidence proper to one "practically unacquainted" with the subject.

I am, etc.,

GEORGE F. BURDER.

Clifton, Nov. 20th, 1853.

MEDICAL STUDENTS.

LETTER TO THE EDITOR.

SIR,—Perhaps, as one of the medical students of Guy's Hospital, I may claim and obtain space in your Journal for a few remarks upon Mr. Davies' letter of December 9th.

I and my colleagues are not aware of any attempt having been made to "convert us as a class into an organised hypocrisy": we are even doubtful as to the exact meaning of the phrase employed. We think that the object and design of our little Association was clearly set forth in Dr. Golding Bird's Christian letter, which recently appeared in your columns.

Never having, in our school days, met with the expression "saponaceous piety", in any classical English writer, we have passed it by, as unworthy of the pen of any member of a liberal profession; and have hoped that some accidental or intemperate haste accounted for its appearance in Mr. Davies' letter.

Far from such an Association tending to divert us from the proper and direct study of medicine, I was grateful to find that all the gentlemen I met there were distinguished by the propriety of their general conduct, conversation, diligence in attention to all the duties of medical students, and that none of us had ever been known to distract the attention of a public teacher by negligence or disrespect; that many with whom I had opportunities of personal intercourse and conversation entertained deep convictions of the responsibility of their calling and profession; and that the motive which led them, thus early in their career, diligently and exactly to perform the duties devolving upon them, was a firm persuasion of the religious obligation so to perform those duties.

It was also very satisfactory to find that the gentlemen who presided over our first meeting were distinguished for their acquirements in science (one loaded with honours from the London University), whose lives have hitherto been free from all approach to selfishness, or unworthy of the principles by which they profess to be actuated.

The subjects introduced to that meeting, for consideration and thought, were by no means the best method of "worming ourselves into families". Far from that: they were the loftiest and noblest principles of morality and religion. The intelligence and information displayed in expanding these to their remote and daily application, though perhaps not quite equal to Mr. Davies' ideas of the capacity of medical students as a class, would, I am sure, have delighted and benefited him as much as they did me. These were affectionately and earnestly pressed upon us; their value and importance were illustrated; and a united wish was felt that our future course through life might be guided by such elevated morality, and humble and conscientious performance of our duties, as the laws of God clearly required.

I think we all were convinced that unkindness to our fellow-students, and in future to our professional brethren, was expressly forbidden to us; that we were not at liberty, even in thought, to attribute unworthy and base motives to them, much less to publish such to the world. We thought also, in reflecting on the tendency of such teaching and advice as was now afforded, that the records of our own profession testified historically the truth of Professor Marx's observation, "that all the great men who had left a permanent impression on our science have been as conspicuous for their religious and moral excellence as for their scientific attainments." If such men are intended by Mr. Davies in his designation of "Mawworms and

Cantwells" (though these are by no means harmonious names), we think that the more our profession abounds with such, the more devoted, generous, disinterested, and enlightened, that profession will become.

We think also that Mr. Davies, on reflection, will find true, what medical testimony almost universally affirms, that a day of rest, even physically, is right, advantageous, and necessary, for the delicate and complicated organisation of man. We think we have found the advantage of rest mentally from the pursuit of professional knowledge, at stated intervals; and Mr. Davies must allow us here, though only medical students, to oppose our own individual experience to his, modestly, yet firmly, as a sufficient answer.

We also cordially agree in the declaration of the medical men who have publicly given utterance to their opinion, that we have no right to devote the sacred rest of the Christian sabbath to the study of Pott or Hunter, or to the pursuit of pleasure and of journeys, too often terminating in sad and ruinous scenes of debauchery.

We also think that we are practically safer at the close of the week in a Bible class, than in incurring the risk of a temptation to the opera, the theatre, or the casino. Instead of loss, we believe that we gain fresh impulse and invigorated motive to renewed and increased diligence in our hospital duties during the ensuing week.

Mr. Davies must allow us to calm his fears and apprehensions of our being led astray by our teachers and advisers; he must allow us to believe, until he or some other shall convince us to the contrary, that the only persistent, constant, safe motive to diligence in our present studies, to honourable, kind, and liberal intercourse with society, are here brought before us with intelligent care for our welfare and future happiness; and we also think that even Mr. Davies, in his calmer moments, will acknowledge the truth of a rule which we are daily taught in the wards of Guy's Hospital, that the abuse of a remedy is no argument against its legitimate and necessary application.

The time allotted to my medical studies is now almost expired; and with regret I shall leave those lecture-rooms and wards where so much research and knowledge have been freely unfolded before me, and where the condescension and urbanity of the medical officers of the hospital on all occasions have produced feelings of obligation and gratitude which can never be effaced. In addition to all these claims upon my respect and gratitude, I have now superadded an interest and care for me in my progress in knowledge of a still higher kind. I am now reminded and encouraged to believe that to all my possible skill and knowledge of my profession may be added the additional excellence of humble Christian piety—a guide through life, a safeguard from the evils of life, and a support in that hour which awaits even a medical man—the hour of his death.

I inclose my name and address.

I am, etc.,

A MEDICAL STUDENT OF GUY'S HOSPITAL.

December 13, 1853.

MEDICAL STUDENTS.

SECOND LETTER FROM FRANCIS DAVIES, ESQ., TO THE EDITOR.

SIR,—“Profound ignorance” I plead guilty to; I unhesitatingly deny that I have objected to proper examination of the Scriptures at suitable seasons. I do object to medical pupils becoming scripture teachers, as it must necessarily interfere with their professional duties. I hate hypocrisy, and will attack the monster whenever I have a chance of grappling with it.

“Fallit enim vitium, specie virtutis et umbrâ,
Cum sit triste habitu, vultuque et veste severum.” JUVENAL.

Trusting I shall never see our Journal merged in the *Evangelical Magazine*,

I am, etc.,

FRANCIS DAVIES.

Pershire, December 12, 1853.

P.S. Your coarse remarks at the end of my letter “require no comment”.—F. D.

[The “coarse remarks” to which Mr. Davies refers will be found at p. 1090. EDITOR.]

CONDITION OF THE FETAL HEAD AT BIRTH.

LETTER FROM EDWARD W. MURPHY, M.D., TO THE EDITOR.

SIR,—I do not wish to interfere in the least in the controversy between Messrs. King and Gaye, on the question respecting the “condition of the foetal head at birth”. I only desire

[* That is, of the results of the Young Men's Christian Association. Ed.]

to explain to them, and to the readers of the JOURNAL, one single point regarding the use of the stethoscope previous to the operation of craniotomy, which Mr. King seems to have misunderstood. He considers it "awful practice" to wait for the death of the child (as ascertained by the stethoscope) before we make up our mind to operate. He considers, where there is a high degree of ossification of the fetal head, the child *in utero* would be likely to retain the vital spark longer than the maternal constitution would hold out; therefore, to be waiting for stethoscopic diagnosis, and listening with the stethoscope till the mother becomes "an inert and lifeless mass", would be "awful practice, and trifling with a valuable life intrusted to our care." (ASSOCIATION JOURNAL, Dec. 9th.) So it certainly would; but is such a practice ever advocated?

Mr. King, however, has fallen into the error of supposing that the practice is advocated. He is speaking of cases where the head of the child is above the brim of the pelvis, where it suffers no great pressure, and when its life is not in much danger.

The professor, to whom I think he alludes, has never recommended such a practice under such circumstances. If, on the contrary, in cases where the head of the child is wedged in the deep conical cavity of a highly ossified pelvis, when the waters are long discharged, when it is impossible to use the forceps, it is then that the death of the child takes place before any symptoms dangerous to the mother arise; and it is then that the stethoscope is most valuable, because by its means the longest possible time is given to nature to expel the child; and it is at once delivered the moment its death is ascertained.

The practitioner is thus relieved from the responsibility of an unnecessary sacrifice of human life, which Mr. King admits to be "awful practice".

For a more clear explanation of my meaning, I can only refer Mr. King to my Lectures (p. 189), in which I advocated the use of the stethoscope "when the head is so impacted in the pelvic cavity, that it would be too hazardous to her safety to attempt delivery by the forceps, and the alternative that remains is to perforate the head, to remove as much of the brain as possible, and to extract the child by means of the crotchet or craniotomy forceps." In these remarks, I have made no allusion to the cases in which an ossified head is above the brim of the pelvis. I am, etc.,

EDWARD W. MURPHY.

12, Henrietta Street, Cavendish Square, Dec. 10th, 1853.

TREATMENT OF POSTERIOR DISPLACEMENT OF THE LENS.

LETTER FROM JAMES DIXON, ESQ., TO THE EDITOR.

SIR,—I have just read, in the JOURNAL of this day (p. 1087), a notice of a paper "On the Treatment of Posterior Displacement of the Lens", which was recently published by me in the *Lancet*. The writer of the notice observes, that by "posterior chamber", Mr. Dixon means the chamber of the vitreous body", as if I were peculiar in attributing such a meaning to the term. I am quite aware that some anatomists describe as "posterior chamber" the space between the iris and the lens; but the words are used by all the standard writers on diseases of the eye, as synonymous with "chamber of the vitreous humour", just as I have employed them. The space between the iris and lens ought surely to be distinguished as "posterior aqueous chamber", and the term "posterior chamber" restricted to the larger space behind the lens.

The writer of the notice says also, that "there is no particular novelty in the operation proposed"; and adds, that he has "performed similar operations, and seen them performed, in like cases, and with rather more success." As the subject has for me a peculiar interest, inasmuch as I wrote my paper under the impression that the operation I described had originated with myself, I should feel particularly obliged if the writer of the notice would, at his earliest convenience, inform me through your columns, where, when, and by whom, the operations he witnessed were performed, and whether any published reports of them are to be met with. I am, etc.,

JAMES DIXON.

Green Street, Grosvenor Square, Dec. 9th, 1853.

RECENT BLACK-BALLING AT THE MEDICAL AND CHIRURGICAL SOCIETY.

LETTER TO THE EDITOR.

SIR,—The astounding fact that a distinguished graduate of the University of London had been refused admittance into the Royal Medical and Chirurgical Society on the ground of not

being qualified, has given rise to an able article from your pen, as well as a meeting of the committee of the London graduates. All who wish the liberal principles upon which this great national university is founded to be fully developed, will rejoice to learn, by the notice of last week, that the committee have decided to take immediate steps to secure the same license to practice for their degrees, which is enjoyed by the degrees of Oxford and Cambridge; and that the senate of the university will adopt a similar course. Nor does there appear any doubt but this will be granted, when we remember that the University of London was founded upon the express covenant with the ministry of the day, that the London degrees should have all the rights and privileges (not of an ecclesiastical order) enjoyed by the degrees of Oxford and Cambridge.

There are, however, certain circumstances connected with this recent transaction which ought to be known, in order that the facts may be duly estimated. For the first time since the granting of the charter to the society, the qualifications of the gentlemen proposed were considered by the council, previous to their names being submitted to the fellows for the ballot. An exception was taken in the council by some of the fellows of the College of Physicians, that an M.D. of the University of London did not qualify the holder to be elected a fellow of the society. This objection was fully discussed, and no motion being made it was considered the objection could not be maintained. After such a decision, it was thought that all would follow the usual course, and consider the members of council as bound by the decision of the majority. But such was evidently not the feeling of the fellows of the College of Physicians alluded to. They succeeded in obtaining a sufficient number of black-balls, on the ground that the candidate was not qualified. It was easy for those gentlemen, armed by the weight of their positions in the Society, thus to influence the election; but whether it was honest or honourable to do so, admits of a great doubt.

Apart from the decision of the council, which ought to have been binding on its members, the statement that the candidate was not qualified could only have reference to two points,—either he was not qualified according to the laws, or by the usages of the society. In both these points, however, the allegation will be found to be incorrect. The law states that "the fellows shall consist of physicians, surgeons, and general practitioners." There is no rule that the fellows must belong to this college or to that; whilst the conventional term "general practitioner" evidently shews that the law was intended to have the widest interpretation. The usages of the society, again, have been to admit qualified medical men without reference to the source from whence they derived their qualification; which is clearly shewn by examining the list of the present fellows. Amongst these there are many who practise as physicians, and who not only do not belong to the College of Physicians, but who do not hold any medical qualification from an English source. Some even only possess the M.D. of a foreign university; but what is still nearer to the question at issue, graduates of the University of London, holding only this qualification, and practising in London, have been previously admitted fellows, without any question being raised as to their qualification.

Further, if the last balloting list be examined, the conduct of these gentlemen appears still more extraordinary. A young student who has just passed the College of Surgeons is considered qualified and admitted a fellow; but a distinguished provincial practitioner, who is an M.D. of the London University, as well as a member of the College of Surgeons, is refused in consequence of a statement circulated in the society to the effect that he was not qualified. It is also very strange that in this same list a licentiate of the College of Physicians is put down as an M.D. of the University of London, who is not an M.D. of any university whatever!

Now no one will deny that it is in the power of any fellow of this society to use the secret agency of the ballot in order to gratify a purpose which he may be ashamed to avow. And all are aware that it is in the power of the society to alter the laws according to the will of the majority. But whilst the laws of the Society remain as they are, it appears almost incredible that gentlemen should league themselves together to injure a younger member of the profession, simply because he happens to be a graduate of the Metropolitan University. If I mistake not, the proposed new charter for the College of Physicians gave to the very men, of whom I complain, the irresponsible power to keep out or admit a large body of physicians who do not at present belong to this College. If this be an example of the way in which the power will be exercised, it behoves the

profession to look carefully into this question, before they subject themselves to unmerited defamation, from the capricious conduct—to use the mildest term—of the individuals referred to.

I am, etc.,
M.D.LOND.

December, 1853.

[We have omitted a sentence contained in the MS. of the above letter of M.D.LOND., because it mentions the names of the gentlemen who are supposed to have taken the lead against Dr. Ransom. In condemning the conspiracy, we did not at first think it necessary to name the conspirators; and we are still of opinion, that as they may regret their conduct, it is better not to do so. The black-balling of Dr. Ransom is not approved by the College of Physicians, nor has it the sanction of the Royal Medical and Chirurgical Society, nor of its Council. It is simply the result of a plot of four or five individuals who have undue influence in both institutions. EDITOR.]

TREATMENT OF CHOLERA.

LETTER FROM G. K. H. PATERSON, ESQ., TO THE EDITOR.

SIR,—There are few, I believe, if any, in the profession, who have not observed that certain impaired states of the constitution are at all times highly prone to take on disease, more particularly during the prevalence of epidemics, from deficiency in the resisting powers of nature; and such are found to make up, generally, a large number of cholera patients. Hence arises their comparatively small chance of recovering when attacked.

I was some time since very forcibly impressed, when reflecting on the apparent deficiency of iron in the blood of persons whom I knew previous to their being attacked with cholera in 1849, with the remarkable fact, that blacksmiths were not, as far as my experience and inquiries have gone, seized with cholera during the time it prevailed. I have thought that they might owe their immunity to the inhalation or absorption of the almost imperceptible particles of iron floating around, and to its oxidation in the blood. This fact has led me to infer, that one obvious cause why so many of the lower classes especially are attacked is a previously existing deficiency of iron and saline matters in the blood, or spæmic condition. When such blood is under the influence of the cholera poison, an imperfect arterialisation immediately commences, which goes on augmenting in proportion to the loss of these materials in the circulation.

In regard to whatever means may be used as a cure, there cannot be the least doubt that the method by which the resisting powers of nature endeavour, often successfully, to expel "foreign morbid matters" from the system is the only true guide that can ever lead to the effectual administration of a remedy fitted alike to counteract the dangerous tendency of the cholera poison, and to assist in throwing it off by the kidneys and alimentary canal.

Believing, then, that the cholera poison is of a highly depressing and malignant nature, it has appeared to me that the sulphates of iron, magnesia, and quinine, and creasote, in combination, from their ascertained physiological actions, are calculated to do great good as a preventive, if not curative remedy, in cholera and diarrhoea. My own success, although limited, makes me desirous of drawing to this treatment the attention of the profession. I am in the habit of prescribing nearly as follows:—

Sulphate of iron, 26 grains.
Sulphate of magnesia, 8 drachms.
Dissolve in water, 4 ounces.
Sulphate of quinine, 30 grains.
Aromatic sulphuric acid, q. s.
Creasote, 5 to 10 drops.
Water, 4 ounces.

Both preparations are now to be mixed together. One or two tablespoonfuls are given repeatedly.

I am, etc.,
GEORGE K. H. PATERSON.

Errol, October 27th, 1853.

TREATMENT OF CHOLERA.

LETTER FROM H. W. REED, M.D. TO THE EDITOR.

SIR,—Perhaps the experience of cholera during a ten years' residence in India, may not be unacceptable to your readers. The following treatment I have found useful, and it has not unfrequently been successful. Immediately upon the first appearance of the disease give a mustard emetic. Do not mind

its being instantaneously rejected; repeat it; and even again, should neither remain longer than three or four minutes in the stomach. If the emetic remains, it will be unnecessary to give another. Since the severity of the symptoms are generally suspended for a time under this management, you have now the opportunity of giving other remedies, without the discouragement of finding them immediately ejected as formerly. Next give half a grain of the muriate of morphia, and three grains of nitrate of potash, every half hour till the pulse increases in vigour and volume, and reaction becomes steady. The first dose of morphia may even be three-quarters of a grain or a grain; or half a grain may be repeated in a quarter of an hour. The case, it must be remarked, is dangerous, and admits not of delay; while to prevent a return of vomiting and collapse is most important. This effected, there is a probability of safety to the patient. Should the vomiting return, try the emetic again, or frequently moisten the tongue with a concentrated solution of morphia. The effect produced, and not the quantity of morphia administered, must form the criterion for its repetition. Sulphuric ether at the same time may be advantageously inhaled from a handkerchief; it tends considerably to allay pain and spasm.

During the course of the disease, at all times allow the patient to satisfy his thirst with copious draughts of water, in which a drachm of carbonate of soda to the quart is dissolved. It will be rendered more grateful and better adapted for the condition of the stomach by the further addition of citric acid. Do not be deterred by its being rejected two or three times, still encourage the patient to drink freely. Foment the stomach with hot turpentine on flannels, or apply large mustard poultices made with turpentine; rub the extremities assiduously with flannels, which may be soaked in turpentine and water. In addition, the bed should be artificially warmed; the spirit lamp so made for that purpose is perhaps the best method. Sixty or eighty drops of laudanum, in an ounce of any bland fluid, may be thrown up the rectum. This should be retained as long as possible, and not repeated unless it has escaped.

The reaction which succeeds in a favourable case to the first violence of the disease is sometimes severe and complicated, and will require its appropriate management.

In cases of British cholera, the morphia and ether, with the mustard externally, will generally be found to succeed in a few hours, even though the disease be attended with cramps and incessant vomiting. No case of cholera can receive a fair chance without the constant presence and unremitting attention of the practitioner.

I am, etc.,

H. WILSON REED, M.D.

Handsworth, Birmingham, October 26th, 1853.

TREATMENT OF CHOLERA.

LETTER FROM WILLIAM I. COX, ESQ., TO THE EDITOR.

SIR,—Dr. Cormack, in doing me the honour to allude in his paper on Cholera (*JOURNAL*, p. 991), to a report of cases published by me in the *Lancet* (January 26th, 1850), says, "five are mentioned as having been treated with sulphuric acid generally in combination with Dr. Ayre's method", etc. This is evidently an accidental error of quotation. The words in the *Lancet* are as follow: "Cases on Dr. Ayre's system, modified by co-administration of sulphuric acid, ice, etc. = 54:—deaths = 13."

In the March number of the *London Journal of Medicine* for 1852, is a report of a paper on the same subject, which I read before the Epidemiological Society, with an abstract of sixty-five cases so treated, with the result of only fourteen deaths. The following table will, however, give at a glance the sum of my experience in the treatment of the malady.

Cases treated by stimulants and opium	17	—	10 deaths.
" " stimulants alone	5	—	3 do.
" " salines	4	—	4 do.
" " calomel on Ayre's system, sulphuric acid and ice	84	—	16 do.

Total 110 33

An analysis shows that the ratio of mortality resulting from the calomel and acid treatment was 19·05 per cent.; while that from other modes, ranged from 50 to 80 per cent. The above cases were all of undoubted cholera. With respect to choleraic diarrhoea, I may mention, that during the past four months I have treated 81 cases (with sulphuric acid alone), with a result of only two deaths.

I am, etc.,

WILLIAM I. COX.

Kensall Town, November 15, 1853.

DR. WEBSTER'S RECENT SPEECH ON THE VACCINATION ACT.

LETTER FROM GEORGE WEBSTER, M.D., TO THE EDITOR.

SIR,—I observe that one or two errors occur in the report of the remarks which I made on bringing forward my resolutions on the Vaccination Act, at the meeting of the Metropolitan Counties Branch of our Association.

I. Though I alluded to the unwieldy and irresponsible General Council of the Association, and its inutility as to any great question affecting the profession, I also said that such a subject came very appropriately after that of medical reform, seeing that the supineness of the medical corporations and their neglect of our interest were practical lessons, which showed the necessity for that reform we had just been discussing. Under a *real* representative system of government in the Colleges and in our Association, such an abomination as the Vaccination Act could not have been perpetrated.

II. I am made to say "eighteen pence is the sum which is put down *even* for paupers", which, as it stands, would not be understood by those not present. The President had asked me, when I mentioned that paltry sum as the fee for vaccination and its attendant trouble, "whether that was for paupers?" My reply was, "Only for paupers," but that it was insufficient even for them; and that such a *minimum* fee became, in fact, the general one in Union practice, and naturally affected all other fees for the same services.

III. In further stating that many respectable people now took advantage of the gratuitous vaccination system, at the different stations in London, connected with the National and other Societies, and that I had no doubt this Bill would very much extend the evil, I am reported as saying that "many of my patients had their children vaccinated at these stations." None of my patients have done this. What I said was, that "*many persons*" did it, and the plan under the new Act of foisting the names of these union or parish vaccinators, upon the parents of every child that comes into the world in future, will have the effect of deceiving the public into the idea that these are the only true, proper, and legitimate vaccinators; and that all others are bunglers.

I may state, in conclusion, that I have conversed with many of the most respectable Medical Practitioners in London, and the course they mean to pursue with respect to this Act, is to have nothing to do with the numerous certificate books sent to them, but by a passive procedure render the act *impracticable*, and thus demonstrate the folly of compulsory injustice.

Considering this plan worthy of all encouragement, and imitation, I am, etc., GEO. WEBSTER.

Dulwich, Dec. 20, 1853.

THE INQUIRY REGARDING GRATUITOUS SERVICES.

LETTER FROM THOMAS CHARLES, ESQ., TO THE EDITOR.

SIR,—Favour me with space to say a few words to numerous correspondents, with whom individually I cannot communicate.

1. The subscriptions to the gratuitous medical services committee, will be acknowledged (with your permission), in the Journal.

2. From the answers hitherto received, I have every reason to expect that a very valuable report will be prepared. I only wish that gentlemen, especially those who advocate things as they are, would be a little less vague in their replies. The committee sincerely desires to produce an impartial and complete report; but if the gentlemen above referred to, do not send more precise answers, giving statistics and stating facts as much as possible, the report will, of necessity, have the appearance of being one-sided. Opinions are valuable, but the committee are still more anxious to obtain facts.

3. Perhaps, there ought to have been a question concerning gratuitous services in connection with Insurance Offices. Of course, opinions and information on this subject would be much esteemed by the committee.

I am, etc. THOS. CHARLES,
Honorary Secretary to the Committee.

5, Lower Belgrave Place, Dec. 21, 1853.

MEDICO-ETHICAL COMMITTEE.

LETTER TO THE EDITOR.

SIR,—Might not the labours of the Medico-Ethical Committee be greatly promoted by members of the Association transmitting their views to the sub-committee who are now at work?

I am, etc., D. W.

[The suggestion is a good one. EDITOR.]

NEWS AND TOPICS OF THE DAY.

OBSCENE BOOKS AND PRINTS. TWO TRIALS IN THE COURT OF QUEEN'S BENCH [Wednesday, December 7th, 1853].

I. THE QUEEN *v.* DUNCOMBE. Mr. Watson, Q.C., and Mr. Clarkson, appeared for the prosecution. The defendant appeared in person.

This was an indictment preferred by the Society for the Suppression of Vice, charging the defendant with the publication of an obscene and indecent book. The defendant lived at No. 7, West Street, St. Martin's Lane. On the 7th October, he sold a book containing some prints to a person employed by the Society, for the sum of two guineas. This book was handed to the jury, and seemed fully to satisfy them of its obscene character.

The defendant addressed the jury, and excused himself upon the ground, that the witness who had proved the purchase of the book, had been nearly twenty times to his shop to purchase other articles (which was not denied by the witness), and that he had been induced to procure the book in question by the offer of a large sum. He vehemently protested that no man had a right to go with his pocket full of money, and tempt a poor man to sell such works.

The foreman of the jury having delivered the verdict of *Guilty*, added a recommendation to mercy.

Lord Campbell, with great warmth, exclaimed, "Mercy! Sir? I should like to know upon what ground? I trust not, for the sake of trial by jury. Recommend to mercy a man who sells poison!"

Several of the jurymen here said they had not agreed to recommend the defendant to mercy.

The foreman said, the ground upon which he wished to recommend the defendant to mercy was, that he believed he had been entrapped into the sale.

Mr. Watson said he would clear up that point, by proving a previous conviction, and what was found in his house when the defendant was taken into custody.

Lord Campbell deferred sentence.

II. THE QUEEN *v.* CANNON. This was a similar prosecution. The defendant wished to retract his plea, and plead *Guilty*.

Mr. Watson said it was in the discretion of the court whether the defendant should be allowed to do so.

Lord Campbell said it would be better to hear the evidence.

Proof of publication on the 29th October, 1852, was then given, and the defendant was found *Guilty*.

Lord Campbell said he was now ready to hear anything the defendants (Duncombe and Cannon) had to say in mitigation of punishment.

Duncombe then put in an affidavit, in which he stated that the convictions which would be put in against him had taken place several years ago, and that the articles seized in his house were locked up.

It was then proposed to put in the convictions, and to give other evidence in aggravation.

Lord Campbell said he should not punish the defendant for what was passed, but the evidence would assist him (Lord Campbell) in apportioning the punishment for the offence of which the defendants had been now convicted.

Evidence was then given, that when the indictment was found against Duncombe, he was arrested, and his house searched. There were found in his house 294 obscene prints, 64 obscene books, 573 obscene songs, 601b. weight of obscene letter-press, and 311lb. weight of stereotyped obscene letter-press.

The defendant said these were all locked up in his drawers, which were forced open by the police.

The Secretary of the Society for the Suppression of Vice produced the record of Duncombe's previous conviction, and proved his identity.

With respect to the other defendant, Cannon, it was proved that in the house occupied by him, there were 2,115 obscene prints, 9 copper-plates, 81 obscene books, and other matters of a most disgusting description.

Lord Campbell made some strong observations upon the moral guilt incurred by the two defendants, which his Lordship observed was greater than that of housebreakers. They sought to earn their bread by corrupting the morals of the people. If they had been led into one solitary act, as was at one time supposed by some of the jury, there might have been room for a lenient sentence; but it was now clear that they were regular traders in obscenity, and had been so for years. Their crime

deserved a very severe punishment; but, as it was in law only a misdemeanour, the sentence upon each of them respectively was, that they be confined in the House of Correction for the county of Middlesex, and kept to hard labour, for the space of two years.

BOARD OF LUNATICS IN PRIVATE ASYLUMS. GREGORY v. BROOKES. [COURT OF QUEEN'S BENCH, November 30.] Mr. Keating, Q.C., and Mr. Maude, appeared for the plaintiff; and Mr. Serjeant Wilkins for the defendant.

The plaintiff, John Gregory, was a barrister, residing in Harley Place, and also the proprietor of a private lunatic asylum at Wyke House, Brentford. The defendant was a parliamentary agent, formerly carrying on business in Bridge Street, Westminster, and residing in Titchfield Villas, Regent's Park. The action was brought to recover for the board, etc., of an insane lady, whom the defendant in January last had placed as a patient at Wyke House. The plaintiff claimed to be paid at the rate of £3:3 a week. The defendant, on the other hand, said he had agreed to pay only at the rate of £2:2 per week. It appeared that the arrangement had been made with the defendant by Dr. Ramsay, the head of the establishment, who stated that he had informed the defendant of the terms, which varied from £2:2 to £5:5 a week, according to the nature of the accommodation and attention required. The charge made was at the rate of four guineas a week for the first four weeks, and three guineas a week for the subsequent period; the lady having had the privilege of a separate room, and other advantages.

The defence was, that the defendant had agreed with Dr. Ramsay that the lady should be boarded at two guineas a week. The defendant said he had expressly stated this at the time the arrangement was made. He added that, as the lady was addicted to cutting up her clothes, he had cautioned Dr. Ramsay not to let her have the keys of her boxes; but that, in defiance of this caution, Dr. Ramsay, without his authority, in the course of three months, supplied her with mercery, lace, and other goods, to the value of £10 odd, which formed one item in the plaintiff's present bill.

Lord Campbell, in summing up the case to the jury, said, the question was, whether the plaintiff was entitled to be paid a reasonable sum for the care of this lady, or whether a special contract had been proved by the defendant? Both the parties were highly respectable; but he (Lord Campbell) thought the defendant was labouring under a hallucination when he said he had made the agreement spoken of. The defendant was not clear whether the agreement was for £2:2 or £2 a week, or for £100 a year. With respect to the goods supplied, his lordship thought that part of the claim could not be resisted. One item the plaintiff could not recover, and that was a fee of two guineas, which had been charged for Dr. Ramsay's attendance upon the defendant, merely to inform him of the terms of the establishment.

The jury found a verdict for the plaintiff for the amount claimed, *minus* the two guineas.

THE VACCINATION ACT IN THE CROYDON UNION. The following advertisement recently appeared in the newspapers:—

"Croydon Union. The Guardians of this Union, not having received any application for the office of Vaccinator for the several parishes within the Croydon district, are still open to an offer from any qualified medical man. It is believed that the population of the district exceeds 25,000; and the Parliamentary amount of remuneration will be in each case, within two miles, 1s. 6d., beyond that distance, 2s. 6d. Further particulars may be obtained on application at my office. Applications must be addressed to me on or before Monday, the 28th instant; and candidates are requested to attend the meeting of the Board at the Workhouse, Duppa's Hill, Croydon, on the following morning at 10 o'clock precisely. (By order of the Board.)

"ALFRED G. BLAKE, Clerk to the Guardians.

"George Street, Croydon, Nov. 22nd, 1853."

In accordance with the above notice, the Guardians assembled on the 28th ultimo. The following minute of what took place has been made public.

"Present:—W. S. Owens, Esq. (Chairman), Messrs. Simpson (Vice-Chairman), Edwards, Farley, Gutteridge, Inkpen, Newton, Reynolds, and Truscott.

"Tuesday being appointed (as per advertisement) for receiving applications from medical gentlemen desirous of being appointed public vaccinators, Mr. Blake reported that he had only received one application, viz., from Mr. Tipple, who was

desirous of being appointed to the Mitcham district. For the Croydon district, he had received no application whatever.

"It was moved and seconded, that Mr. Tipple be appointed vaccinator for Mitcham, on the terms, etc., already stated. Carried unanimously.

"Mr. Edwards was still of opinion (and which he had expressed on a former occasion), that it was desirable to send circulars to the various hospitals of London, for applicants to be appointed. Looking at the extent of the district, numbering now 30,000 souls, such circulars might bring down not one but ten young men, properly qualified to fill the office, who would be willing to undertake its duties. The appointment, he considered, would be a valuable introduction to private practice. He really thought there appeared to be an unwillingness to adopt his suggestion, for fear of giving offence to some persons. For himself, as a guardian, he knew no one, and should, for the reasons he had stated, suggest that that course be adopted.

"In reply to a question, Mr. Blake said that the total number of births in Croydon last year was 744, of which number 437 were vaccinated by the parochial officers.

"Mr. Randolph apprehended that the number of children that would be vaccinated by the public vaccinator in the Croydon district alone during the first year of his appointment would not be less than 600; and moved that 'Mr. Edwards's suggestion be at once adopted.' Carried unanimously."

The following letter appeared on the 17th instant:—

"TO THE EDITOR OF THE SURREY STANDARD.

"SIR,—Sitting as a member of the Croydon Local Board of Health on Tuesday evening last, I was compelled to hear a letter read, purporting to be from the Croydon Board of Guardians, '*requesting that parishioners should be employed by the board in preference to non-parishioners*', in carrying out the large works now in operation for the drainage of the town. You may judge of my surprise at finding that *this* should come from the same Board of Guardians who had on the previous Tuesday elected a stranger as public vaccinator, in preference to the local and resident *rate-paying* medical practitioners, who had indignantly, and, I think, very properly, refused to accept what the guardians chose to denominate in their advertisements '*The Parliamentary Fee*', in other words, the lowest scale allowed by the act, and, I am informed, lower in amount than offered by any other board. I am sorry to say that the terms were accepted for the Mitcham district by a practitioner of long standing, and tendered for by the partner of the senior practitioner of Croydon, who, by the way, considers himself a champion of the profession. This gentleman, however, was not elected, because he had the *audacity* to withhold his application (during the STRIKE, as it was facetiously termed by members of the board) until after the advertisements were published. The fees offered by the Croydon Board of Guardians are one shilling and sixpence for each successful case within two miles of the town, and two shillings and sixpence beyond that distance. This entails the additional necessity of writing three certificates. If unsuccessful, the pay is *nil*. The amount of labour can be judged by any one, knowing that there are thirty-five miles of high road in this parish only.

"I bring this before the public that they, and the profession especially, may see how far the *influence and control of Boards of Guardians* extend. I would complain less, but for want of truthfulness in the whole proceedings of the board, viz., a gentleman is persuaded to risk his reputation, and probably a large outlay of capital, in the expectation that he is to have the introduction to private practice by 600 cases of parochial vaccination. There are sixteen or seventeen general practitioners in Croydon, many of whom have done, and will continue to vaccinate the poor gratuitously [query, will not more do so now?], and will these practitioners, even supposing their patients permit it, allow any Jack Noakes or Tom Stiles to enter their houses at the bidding of any board?

"I am, etc., VERITAS."

ARTIFICIAL PROPAGATION OF SALMON IN THE TAY. The works for the artificial propagation of salmon in the river Tay, at Stormont Bleachfield, on the property of the Earl of Mansfield, and agreed to at a recent meeting of the salmon fishing proprietors, are now completed. There are 300 breeding boxes in all, and two ponds for the reception of the young fry. The works were executed under the superintendence of Peter Brown, Esq., civil engineer, Perth. Operations commenced some weeks ago, under the superintendence of Mr. Rams-

bottom, of Clitheroe, Lancashire, a distinguished pisciculturist, who arrived in Perth on Tuesday, and proceeded on Wednesday morning to Stormontfield. Several gentlemen belonging to the district, as well as from a distance, were present to witness the first operations in trying the experiment of artificially propagating salmon, which has been so successful both in France and Ireland.

MEDICAL ATTENDANCE ON THE POOR IN PARIS. The *Moniteur* of November 22nd published an article of which the following is a translation:—

"An important and salutary innovation in the Administration of Public Aid has been introduced under the direction of the Emperor. Hitherto, a poor person, when attacked with illness, has been scarcely able to obtain relief in any other way but by admission into a hospital; and in this he has not always been able to succeed, on account of the great number of strangers who come by rail from all parts of France, and even from other countries, and who occupy, in the hospitals of Paris, the beds intended for the poor of that city.

"This state of affairs, which continued to become worse, revealed a want which M. Davenne, Director of Public Aid, has provided for by organising the visitation of the sick poor at their own houses. The Council of Supervision and the Municipal Council eagerly adopted this project, which, after having been approved by the Prefect of the Seine, has received the sanction of the Minister of the Interior.

"The following is a very summary account of the new arrangement.

"The number of medical attendants at the *bureaux de bienfaisance* is fixed at 159; they will be distributed among the twelve *arrondissements* in proportion to the indigent population. Their services will no longer be gratuitous: they will each receive a salary of 600 francs (£25) in the central quarters, and of 1,000 francs (£42:13:4) in those parts, such as the *quartier Pepincourt*, the Invalids, Petit Pologne, etc., where the indigent circumstances of the population do not give an opportunity of making a practice, while the distance to be traversed increases the labour of visiting. There will also be in each *arrondissement* paid midwives.

"The medical attendants will be presented by the *bureau de bienfaisance*, and proposed by the Director of Public Aid: they will be elected for six years, and will be capable of re-election.

"Stations will be appointed in the different quarters, at which patients may consult medical officers who will be bound to attend at fixed days and hours, and to remain as long as they may be required to give advice. A member of the *bureau de bienfaisance* will be present on each occasion. The medical attendants will visit at their own houses those who may not be able to attend.

"A register will be opened at the office of each bureau, in which will be inserted the names and residences of all the patients, the date of the commencement of their treatment, and all other necessary information.

"Patients with acute diseases will be visited at least once a week by an administrator or commissioner of public aid, who will enter on a schedule such observations as may occur to him, principally with regard to the medical attendance which the patients are receiving.

"A committee, composed of the president or of a vice-president of the bureau, of a governor or commissioner, of the treasurer of the bureau, and one of the medical officers, will meet every week, to debate on subjects regarding attendance on the patients, and especially on the visiting lists. They will determine what aid it may be proper to afford, in medicine, food, linen, etc., or even in money. In urgent cases, the president may in the intervals advance such aid as is absolutely needed, and of this he shall render an account to the committee.

"Persons not enrolled as paupers, such as needy workmen, persons with large families, or those who are in any way very destitute, will be attended at their own houses, either at their own request, or at the requisition of the mayor or one of the administrators of the bureau in their district, or at the instance of the director of public aid.

"We pass over all in the new regulation which relates merely to administrative measures. We have desired to show the benefit which the poor population of Paris will derive therefrom.

"In future, the hospitals, being disencumbered, will be open for isolated individuals, for strangers attacked with illness at a distance from home, for all persons labouring under severe affections, whose treatment requires the assiduous and devoted care of learned physicians and kind nurses. But the parent of a family will no longer be obliged to leave his domestic hearth, and

to abandon his children, or to leave his daughters exposed to the dangerous suggestions of misery. He who has been prevented from applying to the hospital by a feeling of repugnance will no longer be exposed to suffer without comfort, or to die without help. Again, in many cases, the progress of disease will be arrested by the seasonable administration of remedies, and recovery will be more prompt and sure.

"This useful organisation is already in force in the fifth *arrondissement*, where it has been introduced by M. Vée, formerly mayor, now one of the two inspector-generals of public aid; and the good which has been produced from it is an earnest of the success which may be expected from an extension of the measure into all the quarters of Paris.

"The new regulation will come into force on January 1st, 1854." (*L'Union Médicale*, 22 Novembre, 1853.)

MEDICAL LEGISLATION. MR. BRADY, M.P. for the county of Leitrim, has made known his intentions of bringing into Parliament during next Session two important measures;—viz., a Medical Registration Bill, and a Bill to Amend the New Vaccination Extension Act.

MEDICAL SOCIETY OF LONDON. The following paper is announced.

Saturday, January 7th. The Excretions as Guides to the Administration of Remedies. By Henry W. Fuller, M.D.

ROYAL COLLEGE OF SURGEONS:—PASS LIST. Members admitted by the Court of Examiners on the 16th December:—Messrs. Henry Elmhirst Baxter, Tickhill, York; William Fisher Favell, Sheffield; William Heron, St. Andrew's Street, Dublin; William Frederic Hewington, Hertford; Andrew Harvey, Penzance, Cornwall; Francis O'Donnell, Ballygarry, county Tipperary; Thomas Terry, Bath; John Tearne Holden, Hull, Yorkshire; George Richard Scobell, Henley-on-Thames; James Golden Punch, Cork; Richard Jukes Worthington, Llancaiach, Glamorganshire; William Duke Tidd Ticehurst, Hon. East India Company's Service, Bombay; and James Champion Penny, Fulham.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.]

MERCER, William, M.D., late Lecturer on Anatomy in the Edinburgh Extra-Academical School, at Edinburgh, on 8th December.

PHILP, John, M.D., at Kirkcaldy, N.B., on 8th December.

TRANT, Nicholas, Esq., at 5, Kennington Oval, aged 42, on 14th December.

TO CORRESPONDENTS.

LETTERS. The length and the number of the letters which we receive is a constant source of embarrassment to us. If our correspondents would endeavour to write with more brevity, it would greatly facilitate our arrangements. We have at present unpublished letters on Cholera, Vaccination, Medical Students, and Gratuitous Advice—subjects upon which a large amount of space has already been bestowed—more than sufficient to fill two ordinary numbers of the Journal. The writers will see that we cannot insert these communications without omitting others upon subjects of equal importance. Some of the letters on Medical Students we have, however, reserved for publication.

MR. GUTHRIE'S STATISTICS OF STUDENTS. We have been favoured with a communication from a distinguished surgeon, in which he has drawn our attention to the errors existing in Mr. Guthrie's statistics, on which we offered some comments a fortnight ago. It appears that Mr. Guthrie has assumed that every fresh registration is equivalent to the entry of a new student, whereas every student is compelled to register several times in the course of his career.

MEDICAL METEOROLOGY. Mr. Milner (of Wakefield) requests us to state that he will be happy to furnish any gentleman who may wish to commence a series of meteorological observations, with all the information he can give him.

BINDING THE VOLUME. The numbers ought not to be bound hastily, lest the printing be injured; but sets ought to be completed at once, as the stock is very low. Cases for binding are being prepared. Members wishing copies of numbers to replace those which they have lost, can be supplied either through a bookseller, or by sending the price of the numbers required to the office in stamps.

MEDICO-METEOROLOGICAL OBSERVATIONS*Taken for the Association Medical Journal.***No. XII.—WEEK ENDING 17TH DECEMBER 1853.****WAKEFIELD.** Lat. 53.40.50 N.; Lon. 1.30.26 W.; Height of Cistern of Barometer above the Mean Sea Level, 115 feet.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. LII.

LONDON: FRIDAY EVENING, DECEMBER 30, 1853.

NEW SERIES.

ONE THOUSAND EIGHT HUNDRED AND FIFTY-THREE.

THE close of this year is a proper occasion upon which to glance back at its principal features, and to express the grateful sense which we entertain of the friendly and indulgent manner in which our editorial endeavours have been received. It is not, however, in mere compliance with a customary routine of the season, but with sincere pleasure, that we now tender our hearty and respectful thanks to our colleagues. We commenced our labours by soliciting "co-operation, sympathy, and generous indulgence"; and with all of them we have been most liberally favoured. Though we must confess that the editorial office has proved more onerous than we expected, we must also admit that the performance of its duties has been much more agreeable than we could possibly have anticipated. In all truthfulness we can say, that these duties have been to us a source of real pleasure. The confidential intercourse which we have enjoyed during the past year with so many valued professional correspondents, of all ages, classes, and schools, we have constantly felt, and now gratefully acknowledge as in itself affording no small recompense and reward.

When we entered upon office in January last, there existed in the horizon of the ASSOCIATION many appearances of an unpropitious character, which were peculiarly depressing to our feelings, because we knew, and because the whole profession knew, that they were indications of circumstances which were calculated to alienate a large and influential body of members. We feared that the translation of the JOURNAL to London—the event out of which arose our appointment to the editorship—had been accomplished by so narrow a majority, and after so warm a debate, as to surround our course with innumerable and inevitable difficulties: and, in truth, a glance at our private correspondence of December 1852, and a retrospect of the events and controversies recorded in the Journal of that year, show us even now, that our many fears and anxieties had a justifiable foundation. Participation in these fears, however, by the well-wishers of the Association, prevented their realization, by causing not only a prompt and a general amalgamation of individual opinions, but an increased zeal on behalf of the common good. What was seen by the prophets of evil as a certain cause of disruption and severe trial has proved only a strong stimulant to closer fraternity, and a broad shield from threatened adversity. We expected—and not unreasonably—that our task was to be, for a time at least, to steer the Journal bark amid the surge and swell of contending passions; whereas, it has been far otherwise, and, with the favouring breezes of conciliation, confidence, and kindness, we have hitherto been permitted to navigate her prosperously and peacefully through quiet waters. There has been none of that adverse party spirit which was predicted in so many documents, public and private, as the precursor of constant squalls, and of a

great storm which could not fail to wreck the untried vessel and her too daring crew upon the shoals of Swansea. On the contrary, our endeavours to act faithfully have been received with nearly equal encouragement, and have met with nearly equal support, from those who belonged to the majority and to the minority in the famous division at the Oxford meeting to which we have already referred. Personally, we recognise in this confidence a cause for present gratitude, and a claim upon our greatest exertions for the future. As regards the ASSOCIATION, the spirit of co-operation to which we have referred cannot but be considered as an encouraging sign of essential unity, generous feeling, and augmented power.

These, however, are topics which must be reserved for subsequent discussion. At the close of a year and of a volume, it is more appropriate to give a summary of past events than to anticipate the questions which are looming in the horizon of the future.

Under this impression, we here present to our readers a short chronology of the most remarkable Association and medical occurrences and landmarks of 1853. This can be done without occupying much space, as the copious index which we publish to-day will enable every one to refer to the particular page of the Journal in which the events are described or commented upon.

January 7. The first number of the present weekly series of the ASSOCIATION JOURNAL appeared.

January 11. The First General Meeting of the Metropolitan Counties Branch was held at the Hanover Square Rooms.

January 28. The Journal contained articles which originated important discussions upon the following subjects.

1. Religious Tests in the Scottish Universities.
2. University and Medical Representation in Parliament.
3. Gratuitous Medical Services.
4. Injustice of the Income-tax to the medical profession.

February 18. The Journal contained the report of the honourable acquittal by a court-martial of a medical officer, from the charge of "conduct disgraceful to the character of an officer and a gentleman, in having subjected himself to the indignity of being publicly kicked": [*i.e.*, declining to fight a duel.]

March 1. Anniversary meeting of the Royal Medical and Chirurgical Society, at which a discussion and an event took place, illustrating the peculiar policy and ethics of its Council.

March 11. The first alarm regarding the new Vaccination Act was sounded in the Journal by Mr. King.

March 12. Professor Orfila died at Paris.

March 18. A deputation of the ASSOCIATION, headed by Sir Charles Hastings, waited upon Lord Palmerston to present to his lordship the draft of a Medical Reform Bill, and to request him to introduce it into Parliament as a Government measure.

March 20. Dr. Robert James Graves died at his residence in Dublin.

April 1. No. 1 of a new quarterly journal of medicine appeared in Glasgow, viz., *The Glasgow Medical Journal*.

April 7. Dr. Snow administered chloroform to the Queen in labour. This event, which was first made public through the ASSOCIATION JOURNAL (April 15), gave rise to an important discussion in our pages.

June 7. The "Irish Medical Association" was formed at Dublin upon the model of our own institution.

June 17. An article on the "Strongholds of Quackery in the Fourth Estate" appeared in the Journal; which, in the first place, led to discussions in the Journal and elsewhere; and

then to the establishment, on the 9th Dec., of a society for the suppression of immoral advertisements. The frame-work of this society is nearly completed; and its public operations will commence during the early part of next Parliamentary session.

June 24. Dr. A. P. Stewart announced through the Journal that 640 medical men of London had signed a petition to Parliament, against opening on Sundays, for gain, the Sydenham Crystal Palace. This announcement, and our comments upon it, gave rise to an important discussion in this and other Journals.

July 6. The Earl Manvers laid the foundation stone of the Medical Benevolent College at Epsom, *vice* His Royal Highness Prince Albert, who was confined by an attack of measles.

August 10 and 11. The Twenty-first Anniversary of THE ASSOCIATION was held at Swansea, under the presidency of Dr. G. G. Bird of that town. The new Journal scheme was approved: and a new Medico-Ethical Committee was appointed, composed of the old committee and all the Branch Secretaries.

August 15. The Compulsory Vaccination Act was read a third time in the House of Lords.

August 18. Mr. Bransby Blake Cooper died suddenly at the Athenæum Club.

September 7—15. The Twenty-third Anniversary of the British Association for the Advancement of Science was held at Hull, under the presidency of Mr. Hopkins.

September 30. The threatened invasion of Cholera was discussed at length, for the first time, in the Journal.

October 7. The ASSOCIATION JOURNAL published the first of its weekly Medico-Meteorological Tables.

October 10. The Physiological Section of the Medical Society of London held its first meeting.

October 18. The East Surrey Cholera Society held its first meeting, under the presidency of Dr. Willis.

October 21. The Journal contained complete Statistics of Association Membership.

November 3. The Medico-Ethical Committee of the Association and the Gratuitous Medical Services Committee of the Metropolitan Branch held a conference in London.

November 8. Dr. Ransom was blackballed at the Royal Medical and Chirurgical Society.

December 23. The Journal contained a suggestion (likely to be carried out), to establish in London a Students' Medical Society, for students of all the metropolitan schools.

To many, the perusal of the foregoing brief chronology has doubtless suggested much of what we are about to recapitulate: but nevertheless we may be allowed to give as it were a bird's eye view of what will be found, in various forms, scattered over the pages of this volume, regarding *the causes which prevent the profession of medicine from taking its proper place in public estimation.*

These causes, as we have repeatedly shown, are of two kinds, viz.: 1. *The External*, which have their origin beyond the pale of the profession; and *the Internal*, which have their sources within our own ranks.

The EXTERNAL CAUSES are as follows:—

1. Ignorance of the public, and of those who teach religion, in matters relating to natural science, to the functions of the animal body, and to the preservation of health.
2. Want of representation of the medical profession in Parliament; and, in consequence, on the one hand, the crude and oppressive medical legislation which is inflicted upon us, by new Acts; and on the other, the absence of legal protection for the qualified medical practitioner, and a positive protection for the quack.

The INTERNAL CAUSES are numerous, but the chief of them may be comprehended in the subjoined summary:—

1. Want of uniformity in the education of qualified medical practitioners, and the rivalry of Examining Boards and Medical Schools.
2. Puffing by biographies, books, and advertisements.
3. Underselling our neighbours, and rendering medical services gratuitously to persons who do not stand in need of such alms.
4. The jealousies and unprofessional practices which result from the division of the profession into rival classes, and from the multiplication of special forms of practice.

5. The want of an universally acknowledged code of Medical Ethics, and of a Court of Honour to administer such a code.

This, we admit, is a gloomy catalogue; but we are not among those who give way to despair when we contemplate it. On the contrary, in our Pandora's box, Hope is to be found at the top as well as at the bottom. It is needful, however, that we should from time to time subject ourselves to the penance of looking faithfully at the worst side of medical affairs. It is only by so doing that we can advantageously reconnoitre the battle-ground; keep a steady, watchful eye upon the position of those who oppress us; and so discipline our scattered forces, that our weapons may be always directed against the enemy, and never against our own ranks. We may well be hopeful of the future, when we reflect on the increasing symptoms of unity, revival, zeal, and reformation, which now pervade the Association. If a few succeeding years be as healthful as that which is now closing, we cannot doubt that, ere long, noble and permanent reforms shall be achieved. In the extension, organisation, and purification of the Association, now going on, exist the germinating seeds of future peace, prosperity, and power. That the good work may be carried on with success and vigour, let us unite in maintaining the ASSOCIATION JOURNAL as a free and open arena for the discussion of all subjects connected with medical polity and science; and let us, above all things, strive to make Association membership the unerring test of professional respectability.

THE NUMERICAL STRENGTH OF THE ASSOCIATION DURING 1853.

On the 21st of October, we published a carefully prepared list of the members of the ASSOCIATION, brought down to the 15th of that month. It was compiled with much labour, and corrected in proof by Branch Secretaries and others who kindly aided us in various parts of the kingdom. Some slight errors, which escaped detection, are corrected in the current number. Our object, however, in now returning to the consideration of the numerical strength of the ASSOCIATION, is not merely to rectify a few comparatively trifling mistakes, but to bring down to the close of the year our statistical account of the membership during the currency of 1853. Our colleagues in all quarters thanked us so warmly for our first attempt, and expressed so strong a desire to be kept regularly supplied with information similar to that which it contained, that we have resolved to publish, at suitable intervals, lists of ADMISSIONS, DEATHS, and RESIGNATIONS. The more abundantly information is supplied regarding the state of the ASSOCIATION, the greater interest will members take in its affairs.

On the 15th of October, there were on the list the names of 1926 members, whose subscriptions for 1853 were either paid or due. Since that date, 21 new members have entered. The names and place of residence of these 21 gentlemen are given in the following table.

I. NEW MEMBERS SINCE 15TH OCTOBER.

NAME AND RESIDENCE,	COUNTY.
ANDERSON, W. J., Esq., Welbeck Street, London	Middlesex.
BINDLOSS, James B., Esq., Prestwich	Lancashire.
COUSINS, Edw., Esq., Camden Town, London	Middlesex.
DAVIES, Benjamin, M.D., Brewer St., London	Middlesex.
ERICHSEN, John, Esq., Professor of Surgery in University College, and Surgeon to University College Hospital, Welbeck Street, London	Middlesex.

FENNELL, Edwin, Esq., Wimbledon	- Surrey.
GLEESON, Edward, Esq., Knutsford	- Cheshire.
HARDINGE, Henry, M.D., Sackville Street, London	- Middlesex.
HODSON, George, Esq., Egremont	- Lancashire.
JEANS, J. W., Esq., Grantham	- Lincolnshire.
KESTEVEN, W. B., Esq., Upper Holloway	- Middlesex.
KIRKHOUSE, —, Esq., Clydach	- Glamorgan.
LITTLEJOHN, H. D., M.D., Edinburgh	- Edinburgh.
LODGE, Charles, M.D., Camberwell	- Surrey.
MAHOOD, George, M.D., Enniskillen	- Fermanagh, Irel.
MILNER, William R., Esq., Wakefield	- Yorkshire.
NICHOLSON, John, Esq., Hexham	- Northumberland.
QUAIN, R., Esq., F.R.S., Professor of Clinical Surgery in, and Surgeon to, University College Hospital, Cavendish Sq., London	- Middlesex.
REID, R. B., Esq., Bootle	- Lancashire.
SCOTT, William, Esq., Thornely	- Durham.
WINCHESTER, W. H., Esq., London	- Middlesex.

By adding to the 1926 names formerly published the 21 now given, we have the total names on the roll for 1853, viz., 1947.

We have no means of ascertaining the number on the roll for 1852; but after it had been purged of the names of members who had died and resigned, it contained 1467 names, which were carried at 31st December to the roll of 1853. It is by contrasting the number of members which we are now about to carry over to 1854, with those which we received in January from 1852, that we can most accurately estimate the increase in the *numerical strength* of the Association, which has taken place during 1853. The augmentation in *moral power* can only be fully estimated by a scrutiny of the individual names which have been lost and gained. Resignations and deaths are of necessity in such a body as ours not always real losses, either morally or financially, though they are losses numerically. Again, resignations are sometimes caused by a renunciation of the medical profession; and not unfrequently are only temporary withdrawals, from change of residence, and other slight causes. With these remarks, we must leave the moral valuation to our colleagues, and content ourselves with placing before them a dry numerical estimate.

II. RESIGNATIONS [45] DURING 1853.*

NAME AND RESIDENCE.	COUNTY.
*ALLAN, John, M.D., Islington	- Middlesex.
*APPLETON, John G., Esq., Luton	- Bedfordshire.
*AYRES, Philip B., M.D., Wandsworth Road	- Surrey.
*BATTERSBY, R., M.D., Torquay	- Devon.
*BULLEY, F. A., Esq., Surgeon to the Hospital, Reading	- Berkshire.
*BURGESS, T. H., M.D., London	- Middlesex.
*BUTTER, John, M.D., F.R.S., Plymouth	- Devon.
CARR, William, Esq., Gomersall, near Leeds	- Yorkshire.
COAR, T. T., Esq., Oxford	- Oxfordshire.
*COCKBURN, Archibald W., M.D., Kensington	- Middlesex.
CORNISH, Francis S., Esq., Kingsbridge	- Devon.
DIXON, Thomas, Esq., Preston	- Lancashire.
*FULLERTON, John, Esq., Islington	- Middlesex.
*GARROD, Alfred B., M.D., Professor of Materia Medica in University Coll., London	- Middlesex.
GRIFFITHS, Richard, Esq., Worcester	- Worcestershire.
GRUBB, P., Esq., Warminster	- Wiltshire.
HURT, Samuel, Esq., Mansfield	- Nottinghamshire.
*HUXLEY, J. E., M.D., Medical Superintendent of the Maidstone Asylum	- Kent.
KENDRICK, J., M.D., Consulting Surgeon to the Lying-in Charity, Warrington	- Lancashire.
LAWTON, J., Esq., Chiddingfold, Godalming	- Surrey.
*LOGAN, W., Esq., Milngavie	- Stirlingshire.
*LIDDESDALE, John, Esq., Hungerford	- Berkshire.
*MASKELYNE, Henry, Esq., Faringdon	- Berkshire.
*PENNINGTON, Thomas, Esq., Liverpool	- Lancashire.
*PHILSON, William, M.D., Baldock	- Hertfordshire.

* An asterisk is prefixed to the names of new Members of 1853.

*POLLOCK, Geo. D., Esq., Assistant Surgeon to St. George's Hospital, London	- Middlesex.
RANKING, W. Harcourt, M.D., Physician to the Hospital, Norwich	- Norfolk.
RENDALL, Robert, Esq., Wadebridge	- Cornwall.
SKINNER, William, Esq., Manchester	- Lancashire.
SMART, John C., M.D., Scarborough	- Yorkshire.
SOUTHCOMB, W. T., Esq., Southmolton	- Devon.
SPETTIGUE, John, Esq., Exmouth	- Devon.
*SPICER, N. W., Esq., London	- Middlesex.
SPOONER, E. O., Esq., Blandford	- Dorset.
*SYME, James, Esq., F.R.S.E., Professor of Clinical Surgery in the University of Edinburgh	- Edinburgh.
*SYMES, James F., Esq., Axminster	- Devon.
*TAYLOR, J., Esq., Queen's Road, Bayswater	- Middlesex.
*TOVEY, Charles H., Esq., Maidstone	- Kent.
*TRAVERS, Benjamin, Esq., jun., London	- Middlesex.
TWINING, Edward, Esq., Hull	- Yorkshire.
*WALL, Cavendish, M.D., Dudmaston, Bridgnorth	- Shropshire.
WALTON, H. Haynes, Esq., Assistant-Surgeon to St. Mary's Hospital, London	- Middlesex.
WEST, Thomas, M.D., Daventry	- Northamptonsh.
WORSHIP, J. Lucas, Esq., Riverhead, Sevenoaks	- Kent.
WRIGHT, E., M.D., Shipston-on-Stour	- Worcestershire.

III. DEATHS [18] DURING 1853.*

AINSWORTH, James, Esq., Consulting Surgeon to the Royal Infirmary, Manchester	- Lancashire.
*BARLOW, W. F., Esq., Resident Medical Officer to the Westminster Hospital	- Middlesex.
BATT, Edwin Augustus, Esq., Witney	- Oxfordshire.
CHAMBERS, R., M.D., Physician to the Royal Free Hospital, London	- Middlesex.
CREASY, William, Esq., Edenbridge	- Kent.
DYER, Thomas, Esq., Ringwood	- Hampshire.
FOOKES, Robert, Esq., Stalbridge	- Dorset.
HILL, Joseph, Esq., Knottingley, Ferrybridge	- Yorkshire.
*JAMES, W., M.D., Bristol	- Gloucestershire.
MINES, William, Esq., Diss	- Norfolk.
OUTLAW, Andrew M., Esq., Wellingborough	- Northamptonsh.
*SCOTT, John, M.D., Physician to the Queen for Edinburgh	- Scotland.
SIBBALD, William, M.D., Physician to the Infirmary, Maidstone	- Kent.
STEED, George, M.D., Vice-President of the Association, Southampton	- Hampshire.
STILWELL, Arthur, M.D., Hillingdon	- Middlesex.
*TOMS, William, Esq., Kingsbridge	- Devon.
*WING, Richard, Esq., Barrow-on-the-Hill	- Leicestershire.
WINTLE, F. T., Esq., Oxford	- Oxfordshire.

During 1853, 18 members died, and 45 resigned, making the total loss 63. The following figures will make the state of the case very distinct:—

Members received from 1852	-	1467
Members entered during 1853	-	480
Total members of 1853	-	1947
Resignations and deaths	-	63
To be carried to 1854	-	1884

IT APPEARS FROM THE ABOVE STATISTICS, THAT AFTER MAKING THE REQUIRED DEDUCTIONS FOR DEATHS AND RESIGNATIONS, WE COMMENCE 1854 WITH MORE MEMBERS THAN WE HAD AT 31ST DECEMBER, 1852, BY NO LESS A NUMBER THAN 417. This is far beyond the success which was anticipated by the most sanguine friends of the new system.

On the 1st of January, a list of new members will be formally added to the roll, far exceeding the loss during 1853 by deaths and resignations. This is very encouraging: but it must not be forgotten, that the power and usefulness of the Association cannot be increased by the mere increment of numbers. Membership must be the test of respectability; and irregular practitioners must be weeded out, should any such still remain within our ranks.

A list of new members for 1854 will be published in an early number.

IV. THE NEW MEMBERS FOR 1853.

BERKSHIRE.

Barker, W. R. H., Esq. Wantage
 Bellis, Benjamin, Esq. Maidenhead
 Blomfield, T. A., Esq. Reading
 Brown, G. D., Esq., Resident
 Surgeon to the Hospital Reading
 Bulley, F. A., Esq., Surgeon
 to the Hospital Reading
 Izod, Freeman, Esq. Mortimer, Reading
 Kennard, David, Esq. Lambourne
 Lidderdale, John, Esq. Kintbury, Hungerford
 Luce, J., Esq. Swallowfield, Reading
 Martin, John, Esq. Abingdon
 Maskelyne, Henry, Esq. Faringdon
 Maurice, T. B., Esq., Sur-
 geon to the Hospital Reading
 Moxhay, William W., Esq. Reading
 Royston, Christopher, Esq. Newbury
 Vines, Charles, Esq. Reading
 Weight, Edward, Esq. Wokingham
 Wilesworth, Henry, M.D. Newbury
 Young, William, B., Esq. Reading

CHESHIRE.

Bury, J. Esq. Chester
 Gleson, Edward, Esq. Knutsford
 Godden, Joseph, Esq. Oxtou, Birkenhead
 Gorst, Robert E., Esq. Rock Ferry, Birkenhead
 Kenderdine, T. R., Esq. Macclesfield
 Maund, Henry, Esq. Chester

CORNWALL.

Brougham, Stephen, Esq. Falmouth
 Guppy, T. Stokes, Esq. Falmouth
 Littleton, Thomas, M.B. Saltash
 Moyle, M. P., Esq. Helston
 Rogers, H. J., Esq. Callington

CUMBERLAND.

Graham, John, M.D. Brampton
 Irving, William, Esq. Penrith
 Nixon, Robert, Esq. Wigton

DERBYSHIRE.

Black, Cornelius, M.D. Chesterfield
 Dix, John, Esq., House Sur-
 geon to the Infirmary Derby

DEVONSHIRE.

Balman, Thomas, M.D. Torquay
 Battersby, R., M.D. Torquay
 Bencher, Henry, Esq. Swimbridge, Barnstaple
 Bradshaw, William, Esq. Torquay
 Evans, James, Esq. Torquay
 Pollard, W., jun., Esq. Torquay
 Roper, C. H., Esq. Exeter
 Stewart, William, Esq. Torquay
 Toms, P., M.D. H.M.S. Royal George, Plymouth
 Toms, William, Esq. Kingsbridge [Died 18 Sep.]

DORSETSHIRE.

Williams, Wm. Henry, Esq. Sherbourne

DURHAM.

Clark, Hugh, M.D. Ferry Hill
 Macfarlane, Robert, M.D. Bishop Auckland
 Scott, William, Esq. Thorneley

ESSEX.

Allison, W. J., Esq. Great Hford
 Brown, Thomas, Esq. Saffron Walden
 Cary, William H., Esq. Woodford
 Collins, Frederick, M.D. Woodend
 Doherty, James, Esq. Harlow
 Mingay, Charles, Esq. Dedham
 Tones, Francis, Esq. Havering atte Bower

GLOUCESTERSHIRE.

Allard, William, Esq. Tewkesbury
 Greig, Charles, Esq. Bristol
 Harrison, John, Esq., Sur-
 geon to the Royal Infir-
 mary Bristol
 Hawkins, Thomas, Esq. Bristol

AUTOBIOGRAPHICAL ADVERTISING: BOTH SIDES OF THE QUESTION.

FOR several reasons, it was our intention to have deferred farther remarks upon autobiographical advertising; but as we have received some plausible objections to our opinions, we think it right before the volume closes to exhibit to our readers both sides of the question.

On the 25th of November, we wrote thus:—

"It grieves us to say that in our day the system of pamphlets and circulars adopted by Colbatch and other noted London empirics of the last century, has been revived with even more than its pristine effrontery. Members of our profession of various sorts and conditions, (excusing themselves by the paltry plea of fear of injury from the jibes and slanders of unscrupulous writers), have stooped to write and revise their autobiographies and biographies; and in some cases, regarding which we have information, to circulate by hundreds a self concocted history of self, illustrated by a portrait of self, paid for by self. It would be shallow hypocrisy in us to denounce the minor transgressions of commercial men, and make no allusion to the autobiography system which is now degrading our profession, and so widely corrupting the tone of medical society. It is, we hesitate not to say, unprofessional advertising in its most sickening, most demoralising, and most flagrant form."

We felt the justice of the appeals which were constantly being made to us to endeavour to procure at least an abatement of what we knew to be seriously lowering the profession of medicine in the estimation of the public. We therefore expressed with perfect frankness our sentiments upon the subject, in the article from which the above is quoted, as well as incidentally in recent numbers of the *ASSOCIATION JOURNAL*. Mr. TOWNSEND thinks that our remarks are "injurious"; and as he assigns reasons for so thinking, we publish his letter. His defence of autobiographical advertising is, we think, open to criticism; but in the mean time we shall leave our readers to form their own opinion of its value.

"London, 20th December, 1853.

"DEAR SIR,—You are too hard upon the autobiographers.

"Do they not inform us that they are of noble and ancient lineage; and that the ample domains of their ancestors, who came over with the Conqueror, were confiscated during the wars of the Commonwealth? Such, at least, appears to be the general history of those who have not lost vast wealth by the failure of a bank. Surely, such misfortunes entitle the nobly descended sufferers to proclaim their merits, and to appear before the public on the pages of a Medical Book of Beauty, unscathed by the injurious remarks in which you have wantonly indulged in two recent numbers of the *JOURNAL*."

"I am, etc., JACOB TOWNSEND,

"A lineal descendant of OLD DR. TOWNSEND,
the sole inventor of real Sarsaparilla."

A revised edition of this "Medical Book of Beauty" has been advertised. Shall we review it?

MR. GAY, HIS BIOGRAPHY, AND THE ROYAL FREE HOSPITAL.

WE find in the pages of a cotemporary the following correspondence, which, in justice to Mr. GAY, we think it right to republish in the *ASSOCIATION JOURNAL*. We need scarcely add, that our remarks upon autobiographies referred generally to the system now or lately in vogue, and was not directed against particular individuals. We have reason to know that our remarks have been well received, and that they have already abated some of the evils connected with a method of advertising which we felt, in

common with all our correspondents, to be a grievous scandal to the profession of medicine.

THE SECRETARY OF THE ROYAL FREE HOSPITAL TO MR. GAY.

"Royal Free Hospital, July 15, 1853.

"DEAR SIR,—In conformity with a Resolution adopted by the Committee of Management of this Hospital, I take the liberty of submitting to you the following questions:—

"1. Was the manuscript or proof of your Biography, published in a Medical paper of the date of the 30th of March last, seen by you previously to its publication?

"2. Did you supply any part of that Biography?

"3. If that Biography was published without your knowledge or sanction, have you written to the publisher to complain of any statements or allegations it contained?

"If you will favour me with an early reply I shall be obliged, and am, dear Sir, yours, etc.

"John Gay, Esq."

"W. H. FENN."

MR. GAY'S ANSWER TO THE ABOVE.

"Finsbury-place South, July 19, 1853.

"DEAR SIR.—In reply to your note of the 15th, relative to a Biography of myself which has recently appeared in a Medical periodical, I beg to make the following observations:—

"I supplied the Editor of that Journal with the simple facts of the places of my birth and education, and with such references to my own writings and other works as were required for the compilation of that Biography.

"I am not in any way responsible for the personal or general observations which it contains. I did not either supply or suggest them; I did not see them in manuscript or proof; nor was I aware of their nature prior to their publication.

"I have not complained to the Editor of any statements or allegations contained in that Biography.

"I am, yours truly, JOHN GAY."

PROSPECTS OF THE PROFESSION.

SINCE the publication of a paragraph, entitled "Prospects of the Profession," in our last number, Lord Palmerston has amicably arranged all differences with his colleagues. As a successor had not been appointed, his Lordship had never actually parted with the seals of office. The prospects of the Medical Profession are therefore, so far as can be known, exactly the same as they were before Lord Palmerston's temporary misunderstanding with the other members of the cabinet.

As regards the Medical Reform scheme of the Association, we believe that matters progress favourably; but we have not yet received an authorized version of the Bill for publication in the *JOURNAL*; nor indeed have we received any official communication from the Reform Committee. In these circumstances, members desirous to obtain information or to offer suggestions are requested to send their communications direct to the Secretary of the Committee.

BIBLIOGRAPHICAL NOTICES.

THE PHYSICIAN'S, SURGEON'S, AND GENERAL PRACTITIONER'S VISITING LIST, DIARY, ALMANACK, AND BOOK OF ENGAGEMENTS FOR 1854: upon a Plan furnished to the Publishers by F. S. HADEN, Esq. London: 1853.

THIS is a *vade mecum* of real utility: in fact, after four years' daily use of its predecessors, we feel that *Smith's Visiting List* is an absolute necessary of professional life. We have no particular wish to see anything in the book altered, except the title, which is unnecessarily clumsy. The single word "MEDICAL" would be as expressive, and far more easily pronounced than the present triple prefix to "VISITING LIST". As the blank pages which follow "Ob-

stetric and Vaccination Engagements", for MEMORANDA, must be used for very various purposes by different persons, we think it would be much better to leave the pages without any headings. We have never yet turned these pages to the uses for which they are inscribed, and, among many of whom we have inquired, we have not found one who considered that there was the slightest value in printing such headings as "Certificates given", "New Discoveries", "Extracts", "Advertisements", "Addresses of Patients and Others", "Addresses of Nurses", "Bills asked for", etc. Everybody has his own method of classifying memoranda; and the classes of memoranda required by different persons are very different. For this reason, we submit, that a space for a heading to be written on would be much better than the printed headings which we have quoted.

ACCOUNT OF CASES OF EPIDEMIC CHOLERA TREATED BY HOT WATER APPLICATIONS. By F. A. BULLEY, Surgeon to the Royal Berkshire Hospital. pp. 34. London: 1853.

MR. BULLEY describes in a very satisfactory way some cases of cholera, in which the benefit of warm applications to the surface is demonstrated. The pamphlet is highly creditable to its author, and deserves to be regarded as a good contribution to the literature of cholera therapeutics.

SURGICAL ANATOMY. By JOSEPH MACLISE, Fellow of the Royal College of Surgeons. [Second edition.] Fas. I and II. Folio. London: 1853.

THIS is the second issue of a work which has acquired great and well merited popularity, from its possessing in a high degree the recommendations of elegance, accuracy, and economy.

EDITOR'S LETTER BOX.

MEDICAL CERTIFICATES OF INSANITY.

LETTER FROM JOHN WARWICK, Esq., TO THE EDITOR.

SIR,—The new Act of Parliament "for the Regulation of the Care and Treatment of Lunatics" (16 and 17 Vict., cap. 90), enacts important changes in the matter of Medical Certificates of Insanity. Section 46 of the former Act (8 and 9 Vict., cap. 100) allowed the medical practitioner to certify the insanity of a person upon the information of a third party: it ran as follows:—"That every physician, surgeon, or apothecary, signing such certificate, shall specify therein any fact or facts (whether arising from his own observation, or from the information of any other person) upon which he has formed his opinion," etc.

Section 3 of the new Act repeals the foregoing, and substitutes the following for it:—

"Sect. 10. Every physician, surgeon, and apothecary, signing any certificate under or for the purposes of this Act, shall specify therein the facts upon which he has formed his opinion that the person to whom such certificate relates is a lunatic, an idiot, or a person of unsound mind; and distinguish in such certificate facts observed by himself from facts communicated to him by others; and no person shall be received into any registered hospital or licensed house, or as a single patient, under any certificate which purports to be founded only upon facts communicated by others."

Hence it follows that a certificate of lunacy, founded wholly upon facts communicated by a third party, will no longer authorise the reception of a lunatic into any asylum. The design of this change in the law is praiseworthy, it being intended to afford additional protection to the liberty of the subject, and some doubtful lunatics may be gainers by it; but whether the change is equally calculated to afford protection to the family and friends of a supposed lunatic, and to society at large, time will show.

It is to be presumed that our legislators, and those who directed their judgment in this matter, had sufficient reasons for making so important an alteration; and it would be instructive to know what those reasons were. Did the former regulation

on this point lead to grave abuses? Were many persons unjustly confined in asylums under it? If such was the case, the belief generally entertained by persons interested in the subject is erroneous; for it has always been reported that the Commissioners in Lunacy have met in their visitations with very few instances of sane persons improperly received into an asylum upon false or dishonest medical certificates. For my own part, I entertain serious apprehensions that the change in question will prove productive of mischievous, perhaps fatal, results.

There is a species of insanity, in the language of the day, termed *emotional*, which comprises the "moral insanity" of Dr. Prichard, and the numerous varieties of *instinctive* or *impulsive* madness. It is a form of the disease which seems to affect the passions more than the intellect, and which manifests itself rather by action than in language. It is frequently productive of phenomena which more closely resemble the effects of moral depravity than of intellectual aberration, and furnishes those painful cases in which justice is called upon to define the boundaries of human responsibility. It is mainly in its relation to this particular class of mental derangement that I consider the recent change in the law respecting medical certificates to be injudicious. No kind of insanity is so difficult to detect in its latent form—none more dangerous and distressing in its active manifestation. The objective symptoms of the malady are frequently not only sudden in their invasion, but also of brief duration; the subjective indications being faint and obscure, and often carefully and cunningly concealed. The unfortunate sufferer is usually sensible of his own mental infirmity, but retains sufficient self-control to hide it from others, and especially from strangers. Many of these *apparently rational* individuals urgently require the curative treatment which a well conducted asylum best affords; but, under the new Lunacy Act, it will be difficult in certain cases to obtain, by personal observation, sufficient indications of insanity to warrant their consignment thither.

To illustrate this difficulty, I will briefly relate the leading particulars of a few cases which have come under my notice in the course of practice.

CASE I. A married lady, of brilliant talents, and highly accomplished, became maniacal during an attack of fever. The stage of excitement lasted for a period, and then gradually subsided, leaving her apparently free from any mental lesion. After much consultation, she was set at liberty, when it became apparent that, although her intellect had recovered, her moral sense was irretrievably lost; for she at once voluntarily commenced leading a life of debauchery, and soon brought herself to an untimely end. In the midst of her wildest excesses, this lady remained so free from intellectual aberration, that no medical practitioner could have certified her fitness for confinement in an asylum, unless he could personally have become acquainted with her depraved behaviour.

CASE II. A single lady, of cultivated mind, somewhat eccentric, but showing no particular delusions, rational in conversation, and usually correct in conduct, is liable at intervals to be seized with an uncontrollable impulse to commit violence upon others. Whilst under the influence of this impulse, she will assault any person near her, and, at different times, has injured various members of her family. The paroxysm lasts only a few minutes; she then becomes calm and rational, and denies all knowledge of the preceding act. The difficulty of certifying from personal observation, in such a case, is obvious.

CASE III. A gentleman, having an hereditary predisposition to insanity, married a high minded and excellent lady, some few years older than himself. For awhile he was a devoted husband; he then grew indifferent, and subsequently commenced treating his wife with deliberate and systematic cruelty. At the same time, he became very intemperate, and indulged in all kinds of excesses. His conduct towards his wife was so notorious, that his servants and neighbours all considered him deranged; yet he laboured under no delusions, and was so rational in conversation, that a physician of eminence refused to certify him as insane, when requested to do so by his family. From personal knowledge, I have no hesitation in pronouncing this gentleman to have been a dangerous lunatic; yet the law, in its present state, would not permit his reception into an asylum.

CASE IV. A gentleman, possessing many polite attainments, a fair amount of intellectual culture, and an amiable wife, was afflicted with a diseased activity of the sexual instinct. He would make improper overtures to every female whom chance threw in his way, and, whenever an occasion offered, would gratify his filthy and depraved propensities in a manner and to an extent barely credible. Public morality and private decency

require that such a person should be confined; yet this gentleman had no positive delusions, and had such command over his language and behaviour as would have rendered the detection of his malady a very difficult matter, had he himself sought to conceal it.

CASE V. A gentleman, a few months after marriage, conceived unfounded suspicions of his wife's fidelity. Actuated by this feeling, he treated her with great harshness and severity, and frequently resorted to personal violence. Finally, he made an attempt upon her life. Yet, during this time, he conducted himself rationally towards other persons, and manifested no other delusion. Ultimately, further symptoms of insanity developed themselves, and he was placed under restraint. In this gentleman's case—by no means a solitary instance—the testimony of the wife was for a time the sole evidence of his mental malady; yet, as the law now stands, such evidence would be insufficient to procure the confinement of a person so affected.

CASE VI. A gentleman, suffering from gastric derangement, but apparently free from any mental affection, attempted self-destruction by strangulation. Fortunately, he was observed, and prevented accomplishing his purpose. Immediately afterwards, he positively denied all suicidal intention, and appeared rational and collected. A person in this state of health should undoubtedly be placed under such surveillance as an asylum alone affords; but this step could not be legally taken under the recent enactment, which virtually restricts the proof of insanity to the personal testimony of a medical practitioner.

CASE VII. A farmer, unmarried, some of whose relations were insane, contracted intemperate habits at an early age. He was naturally passionate and impulsive, and obviously deficient in stability of purpose and power of self-control. At times, he grew sullen and reserved, and carried a razor in his pocket. When about forty years of age, he began to evince a dislike to his mother, with whom he resided; and frequently made use of alarming language towards her. On one occasion, he proceeded to actual violence, dashing a loaf of bread in her face, and threatening to cut her throat. He was not intoxicated at the time. After this, he was placed in an asylum, under medical certificates which would not now be legal; but, neither at the time of his admission, nor during the four months of his detention, did he betray the slightest symptom of disordered intellect. His mind seemed ill regulated, and he was fretful and discontented; but he manifested no delusion, and always conversed and conducted himself in a rational manner. In this case, the impulse to violence was clearly induced by indulgence in spirituous liquors; but it did not proceed immediately from intoxication, and was not the result of delirium tremens.

If further illustration were needed, I could relate other examples, but I think I have quoted a sufficient number of cases to exemplify the subject-matter of this communication, and to substantiate the grounds of my misgiving touching the unfavourable operation, in certain cases of impulsive insanity, of the late changes in the law relating to medical certificates.

I am, etc. JOHN WARWICK.

Laverstock House, near Salisbury, Dec. 22nd, 1853.

MEDICAL METEOROLOGY.

LETTER FROM T. HERBERT BARKER, M.D. TO THE EDITOR.

SIR,—If any one had required me to mention a scheme of scientific investigation the least likely to excite controversy, I should have named the plan of recording *daily* meteorological observations side by side with the cases of diseases and deaths occurring on those very days, as pre-eminently *non-controversial*. It appears, however, that I am mistaken; and that, however unexpected and distasteful it may be, I am most unwillingly drawn into a controversial style of writing.

On carefully looking through Dr. Burder's last letter, I find very little additional matter to notice. If the first letter displayed a "strange kind of logic", the second shows no very great improvement in logical style. Your correspondent has somewhat shifted his ground. In his *first* letter there was no allusion whatever to the difficulty of getting precise information of the commencement of diseases; *now*, however, he advances this objection in a formal and logical style.

If your correspondent at first laid himself open to the charge of knowing but little of practical meteorology, it now appears that his practical acquaintance with diseases is as slight. There can be no doubt that the *precise day of seizure of most of the acute diseases—yea, the very hour of many of them—can be correctly and rigidly ascertained*. Where we have the slightest doubt as to the precise day, the disease is not recorded.

I deny that "changes of temperature are not fully felt within doors until many hours, or even some days, have elapsed."

Let your correspondent ask the first meteorological friend he meets, if we may not have a difference of 20°, or more, in the temperature of two consecutive days or nights; then let him ask any judicious housewife if she would have the same amount of fire kept up within doors, with the temperature as indicated by the thermometer one day at 50°, and another at 30°; or if she would use the same amount of bed-clothing for her children one night, with the temperature at 40°, or more, and another at 20°. Let him then inquire of some practical medical friend, if he had not observed every member, or a majority of the members, of large families, rise in the morning indisposed, having retired in perfect health the night before; again, if he had not frequently met with an almost sudden accession of many cases which had occurred within doors during the preceding few hours: if he had not observed numerous cases in some particular streets, in some parts of towns, in whole villages, coming on simultaneously, and within doors, during a single night; and if he had not so frequently noticed these coincidences, as to attribute them to atmospheric changes. He will, moreover, inform your correspondent that these changes will show themselves within doors, much sooner than he seems inclined to think they do. Every practical man will be familiar with so many instances of this kind, that it will be unnecessary to dwell further upon the point.

Your correspondent must bear in mind that our plan is that of *daily*, not *hourly*, observations; although occasionally, during extraordinary meteorological fluctuations, or during periods of unusual progress of disease, *hourly* observations would be desirable.

We prefer the record of *daily* observations and diseases and deaths. If your correspondent prefer *weekly means*, he may adopt that plan; he may, moreover, make our tables subservient to his own purpose, if he will take the trouble to deduce the *weekly means* from our daily observations. We have not done this, because we think the daily plan embraces all the advantages of the other, and some grand excellencies besides.

For the table of figures which your correspondent criticises, I was indebted to Dr. Moffat of Hawarden, and therefore leave that gentleman to meet the objections in his own satisfactory manner.

"Hawarden, December 24th, 1853.

"MY DEAR SIR,—It appears by a letter in the ASSOCIATION MEDICAL JOURNAL of to-day, that two errors have been discovered in a table in an article on Medical Meteorology, which appeared in that Journal a few months ago. The errors are accidental. On referring to the original tables, I find that the numbers are—epistaxes, with increase of the readings of the barometer, 37·5; with decrease, 62·5; with ozone, 50·0; with no ozone, 50·0; and toothache, with increase of the barometer readings, 19·4; with decrease of the readings, 80·6.

"It also appears that the author of the letter does not understand the wind columns of the table. I beg therefore to offer the following explanation. The numbers in these columns are not the *per centage of cases of diseases and of deaths with the directions of the wind*, they are the *number of cases for 100 times the wind was in each point of the compass*. The necessity for such an arrangement must be obvious to everybody. For example—from the following table, *without noticing the number of times the direction of the wind was from each point*, it would appear that the number of diseases with a W. wind, are the same as those with a S.E. wind; and that the number of deaths are greater with a S. than with a N. wind. But, *taking the number of times the wind was from these points into the calculation*, how different the result appears.

TABLE.

Points of the compass..	N.	N.E.	E.	S.E.	S.	S.W.	W.	N.W.
No. of times the wind was from each point..	40	30	20	100	100	170	160	150
Number of diseases....	0	0	0	80	0	0	80	0
Number of deaths....	60	0	0	0	70	0	0	0
Per cent., or number of diseases for 100 times the wind was.....	0	0	0	80	0	0	50	0
Per cent., or number of deaths for 100 times the wind was.....	150	0	0	0	70	0	0	0

"I trust this table will be intelligible.

I am, etc.

"Dr. Barker."

T. MOFFAT."

To conclude; I cannot admit that your correspondent has detected any error in reference to the main designs of our plan.

nor has he favoured us with any suggestions of the least value that I can discover. If he still thinks *weekly means* are the more valuable, he can procure them for himself. We do not think so, and therefore do not adopt them.

Apologizing for thus troubling you, I will merely add, that unless something very specially requires notice, I shall not again trouble you on this subject. I am, etc.,

T. HERBERT BARKER.

Bedford, 26th December, 1853.

MEDICAL STUDENTS.

LETTER TO THE EDITOR.

SIR,—As one of the oldest medical teachers in London, I hope you will permit me to express my entire sympathy in your remarks on the proposal of Dr. Golding Bird, for promoting the religious training of medical students. I can bear my testimony to the great improvement that has in this respect taken place in the metropolitan schools in the last quarter of a century, not only as regards the students, but also their teachers; ribald jests and profane allusions, which in former years occasionally debased the professorial chair, would now, if hazarded, receive rebuke rather than applause in all well-ordered institutions. As an indication of the deep change that has for years been progressing, I may state, what you, Sir, are doubtless acquainted with, that many distinguished teachers, London and provincial, are anxious to establish a Christian Medical Society, with branches in each school; and when it is known that such sentiments as are expressed by "A Medical Student of Guy's Hospital" (see p. 1138 of this Journal) extensively prevail among the body of pupils at large, we may well hope that, under the Divine blessing, the effort now being made will be crowned with success. Your readers will not, I feel assured, allow their judgment to be warped by erroneous representations as to the objects of such an association. For myself, I can conceive of no proposal more promising, not only as regards the medical student, but society at large, than one which aims at diffusing among the rising members of our influential profession, the precious truths of Christianity. That the habitual study of the revealed word of God, and a zealous desire to communicate to others a saving knowledge of the gospel of peace, is neither incompatible with the highest attainments in science, nor with the most conscientious discharge of professional duties, might be shown by many brilliant examples in this and other countries. It is thus that the studies and pursuits of our profession are consecrated; and happy will it be for mankind when the truth of the aphorism enunciated by the illustrious founder of electro-magnetism, Oersted, is recognised by every professor of the healing art, that "the man of science must ever look upon his pursuits, if he understands them rightly, as a constant exercise of religion." With much respect, I am, etc.,

F. R. S., AND A MEMBER OF THE ASSOCIATION.

Christmas Day, 1853.

MEDICAL STUDENTS:—AN EXPLANATION.

LETTER FROM FRANCIS DAVIES, ESQ., TO THE EDITOR.

SIR,—If you will have the goodness to insert this note, I do not intend to intrude myself again on your notice.

In the first place, if I have written one word that has given pain, I beg to retract it, and to express my sorrow. The purport of my letter has been so much misunderstood, that I am most anxious to explain what I really meant.

What I object to is, that Medical Students should trench on the duties of another profession, for which I contend they are wholly unfit. I never did object to their attending sedulously to their religious duties, at proper times and suitable seasons. I did not advise them to read Percival Pott or John Hunter on Sundays. I do not think these names are to be mentioned without respect: John Hunter was one of the greatest men this world ever saw; and Pott the most classical and elegant of surgical writers.

I am an old Arctic voyager; I have also served on the Coasts of Africa, and North and South America—and under too strict a disciplinarian for me ever to inculcate insubordination to existing authorities. I hold that students should implicitly obey their teachers.

I have recently received very many tracts, pamphlets, and sermons, with quantities of good wishes; but not one of the senders has had the manliness to add his name. I fancy I could not have been a very inattentive pupil: I was cotemporary with the present President of the College of Surgeons, who

deservedly stands at the top of that profession of which I am the humblest member.

I am, etc., FRANCIS DAVIES.

Parsloore, Dec. 28th, 1853.

[The previous letters of Mr. Davies will be found at pages 1090 and 1138. EDITOR.]

TO CORRESPONDENTS.

THE SECRETARIES OF THE BRANCHES will much oblige the Editor by forwarding immediately to him the names of all the officers of their respective Branches, for publication in the first number for the ensuing year.

ADDRESSES OF MEMBERS. Members who desire any change to be made in the addresses of their Journals, are earnestly desired to communicate the same, without delay, to the publisher, Mr. Honeymann. Gentlemen who propose new members ought to furnish the correct postal addresses *distinctly written*.

ECONOMY IN BINDING THE VOLUME. Members and others can be supplied with STRONG CASES, lettered on the back, for binding the volume completed by the present number. Price at the office, or through any bookseller, ONE SHILLING AND SIXPENCE. Gentlemen may for HALF-A-CROWN have a case and also their numbers bound up in it. Carriage must be paid both to and from the office. As the stock of some of the numbers is nearly gone, gentlemen who wish to complete their sets are recommended at once to purchase the numbers they require, either at the office, or through a bookseller.

ERRATA IN LIST AT p. 915, AND CHANGES OF ADDRESS.

[The words within brackets ought to be inserted.]

BANNING, T. H., M.D., late of Oswestry, has removed to Widnes, Warrington, Lancashire.

BARRATT, Joseph G., M.D., late of Ross, Herefordshire, has removed to Bath.

BEEVER, William W., Esq., Manchester, should have had *c* prefixed to his name.

BROWN, C. F., Esq., late of Bathford, Bath, has removed to Carlton Villas, Clifton.

BROWN, G. D., Esq. [Resident Surgeon to the Hospital], Reading.

BUCKLEY, A. G. H., Esq., late of Rugby, has removed to Market Harborough, Leicestershire.

BUSH, W., M.D., late of Weston-Super-Mare, has removed to Rosen Vale, Ludgvan, Penzance, Cornwall.

COLLINS, Frederick [M.D.], Wanstead, Essex.

COLLYNS, William, Esq., of Harlow, Essex, removed to Drewsteignton, near Exeter.

CORLEY, Robert R., Esq., Lanehead, Suffolk; read CARLEY, R. R., Esq., Laxfield, Framlingham, Suffolk.

COTTON, Charles, M.D., Lyme Regis, having resigned in 1852, and re-entered in 1853, ought to have had *n* prefixed to his name.

COWAN, C., M.D., [Consulting] Physician to the Hospital, Reading.

ELLIS, H. W. T., Esq., Crowle Hall, [by Bawtry] Lincolnshire.

FIELD, John J., M.D., late of Torquay, has removed to Oxford.

GODFREY, Race, Esq., late of Islington, has removed to Bath.

HARRISON, I., Esq., [formerly] Surgeon to the Dispensary, Reading.

HUGHES, [William] Esq., Llanrwst, Denbighshire.

IKIN, J. Ingham, Esq. [Lecturer on Anatomy and Physiology, Surgeon to the Hospital for Women and Children], Leeds.

IZOD, Freeman, Esq. [Mortimer], Reading.

JONES, J., Esq., Amman Iron Works [Llanelli], Carmarthen

KEMPTON, P. Tertius, Esq., late of Brierly Hill, Dudley, Worcestershire, has left England.

LANE, C. H. Butler, M.D., late of Brighton, has removed to Newton Bushel, Devon.

MASFEN, William E. [M.B.], Stafford.

O'CONNOR, William, M.D., late of George Street, Portman Square, has removed to Montague Street, Montague Square.

OGLE, William, Esq., late of Cambridge, has removed to Chester Terrace, Eaton Square, London.

PRICE, Jones, Esq., Rhyl, Flintshire, should be JONES, Price, Esq.

POWELL, R. H., M.D., late of Edwards Street, has removed to Somerset Street, Portman Square.

ROBERTS, P. N., Esq., late of Denbigh, has left that place.

SCHOLFIELD, E., M.D., Doncaster. For "Consulting Surgeon", read "Consulting Physician".

SOMERVILLE, Charles [M.D.], Walsall, Staffordshire.

TAYLOR, Robert [Esq.], Guildford Street [Surgeon to the Central London Ophthalmic Hospital].

VERTUE, [Francis] Henry, Esq., Southwold, Suffolk.

INDEX.

- A.
Abernethy, John, F.R.S., Mr. Macilwain's Memoirs of, *rev.*, 1110
Abortion, production of, shows necessity for medical reform, 410; trials for procuring, 715; partial, in a twin pregnancy, 997
Abrahams, Dr. S., oxygen, an antidote in poisoning with chloroform, 819
Abscess in bone, Mr. H. Lee on, 7; in brain, case of, 102; in pelvis, Dr. Tyler Smith on, 514
Academy of Medicine, foreign associates of, 245
Acne tuberculosa, umbilicated, 307
Aconite, case of poisoning by, near Bristol, 71; Dr. O'Brien on, 92; Mr. Griggon, 136; cases of poisoning by, 817, 1040
Adams, Mr. John, case of scirrhus of prostate, 379
——— Dr. Mercer, congenital displacement of head of femur, 931
——— Mr. William, aneurism of posterior tibial artery treated by perchloride of iron, 724
Addison, Dr. William, on meteorology, 80
Adulterations of food and medicines, 116; of drugs, Mr. Peirce on, *rev.*, 642
Advertisements, fraudulent and obscene, leading articles on, 518, 631, 660; medical, specimens of, 912; puffing, 1027, 1177
Advice, gratuitous, abuses of, 76, 201; letters on, 493, 533, 641; letters in defence of, 493, 1070, 1071, 1072, 1095; appointment of Committee on, by Metropolitan Counties Branch, 654; questions issued by Committee on, 998; to members of the Association, 1008, 1044, 1049. *See* Clubs, Hospital Abuses, and Physicians
Agardh, M., formation of the cell-membrane, 109
Aillaud, Dr., turpentine vapour-baths, 801
Ainsworth, Mr. James, memoir of, 1044
Air, cases of entrance of into veins, 91, 466; compressed, bath of, Mr. Poyser and M. Milliet on, 797; M. Pravaz on, *rev.*, 1038
Albers, Dr., on theine and caffeine, 156
Albuminuria, ozone in treatment of, 91; cases of, 126; in pregnant females, 64; symptoms, 64; mechanical origin, 65; relation to renal diseases, *ib.*; prognosis, *ib.*; relation to puerperal convulsions, 63; other toxicæmic effects of, *ib.*; treatment, *ib.*
Alderson, Dr. James, on Acute Rheumatism, *rev.*, 775
Alkaloids, detection of, in cases of poisoning, 946
Allohin, Mr. A., on compound extract of colocynth and compound colocynth pill, 135
Alford, Mr. R., case of mortification of leg, 166
Alison, Dr. Scott, on Medication of Larynx and Trachea, *rev.*, 525
Allen, Mr. G., death from the bite of a cat, 719
——— Rev. H., on table-turning, 822
——— Mr. James, on parliamentary representation of medical profession, 24
——— Dr. P., on Deafness and Diseases of the Ear, *rev.*, 834
Allison, Mr. W., on Sunday at the Crystal Palace, 693
Alopecia, cases of, 902, 929, 1044
Amaurosis accompanying disease of heart, 241
Amblyopia, presbyopic, M. Sichel on, 880
Amenorrhœa, cases of, 128
Ammonia, hydrochlorate of, in enlarged prostate, 397; carbonate of, in snake-bite, 597; in glanders, 643
Amputation of arm of a child, 35
Anæsthesia. *See* Chloroform and Ether.
Anæsthetic, Mr. Richardson on puff-ball as an, 479
Anatomy, Dr. Knox's Manual of, *rev.*, 39; Messrs. Ledwich's, *rev.*, 304; preparations of, Mr. Goodsir on, 676
Ansell, Mr. H., on Tuberculosis, *rev.*, 88; on tuberculosis, 853, 894, 1030
Anderson, Mr. W. J., on Hysteria, *rev.*, 238; nitro-sulphuric acid in diarrhœa, 664
Aneurism, Mr. Turner on pressure in, 616; injection of perchloride of iron in, 1082; of aorta, Dr. R. H. Powell on, 232; of aorta, opening into pulmonary artery, 683; popliteal, 572, 1010; traumatic of ulnar artery, 573; cirroid, 306
Anthelmintics, relative value of, 134
Anus, imperforate, case of, 670
Aorta, aneurism of, Dr. R. H. Powell, on, 232; Dr. F. J. Brown on, 293; Dr. Cowdell on, 539; cases of, 583, 1010
Apoplexy, in a fœtus in utero, 92; in a boy, 101
Apothecaries' Hall pass lists, 312, 387, 476, 496, 556, 576, 604, 764, 864, 938, 1097; regulations of, 839
Appointments, 74, 114, 180, 226, 263, 340, 387, 408, 448, 476, 496, 516, 536, 556, 604, 658, 710, 744, 764, 864, 912, 1025, 1073, 1097
Apprentices to trades, medical examination of, 159
Aquatic vivarium in Regent's Park, 555
Aran, Dr., chloroform in lead-colic, 18; collodion in ulceration of cervix uteri, 468; tincture of iodine in typhoid fever, 549
Arcus senilis in relation to heart disease, Dr. Haskins on, 238
Army medical officers, dinner of, 496
Arnott, Dr. James, on Local Application of Cold, *rev.*, 303
Arrowsmith, Mr. J. Y., on hospital abuses, 447
Arsenic, in cholera, 91; in chronic scabies, 301; in snake-bite, 812; cases of poisoning by, 105, 818, 878; distinctive characters, 948; antidote to, *ib.*
Artery, external iliac, ligature of, by Dr. Ogden, 309; by Mr. Denne, 572. *See* Aneurism.
Ash, therapeutic uses of, 17
Ashley, Dr. W. H., hemiplegia from exposure to solar heat, 149; acute intestinal tuberculosis, 439
Ashton, Mr. T. J., on Corns and Bunions, *rev.*, 209
Asphyxia, Mr. Jennings on warm bath in, 348
Association, British, for Advancement of Science, 860, 884.

 Bernays, Mr. A. J., Household Chemistry, *rev.*, 90
 BIBLIOGRAPHICAL NOTICES:—Alderson (J., M.D.), Pathology and Treatment of Acute Rheumatism, 775; Alison (Scott), Medication of the Larynx and Trachea, 526; Allen (P.), on Deafness and Diseases of the Ear from Small-pox, etc., 834; Ancell on Tuberculosis, 88; Anderson on Hysteria, 238; Arnott (Jas.), Local Applications of Cold, 303; Ashton on Corns and Bunions, and Ingrowing of the Toe-nail, 209; Auzias-Turenne on Cholera and its Treatment, 1068; Bascome on Nature and Treatment of Cholera, 1067; Belcombe (H. S.), Essays, 721; Bennet (Henry), Inflammation of the Uterus, 641; Bennett (Hughes), Introduction to Clinical Medicine, 39; Bernays, Household Chemistry, 90; Billing on Diseases of the Lungs and Heart, 169; Bird (Golding) on Urinary Deposits, 260; Bird (James), What to Observe in Medicine, 16; Black (C.), Pathology of Bronchio-pulmonary Mucous Membrane, 706; Blacklock, Treatment of Intermittent Fever by Phosphate of Lime and Sulphur, 107; Branstons' Druggists' Handbook of Practical Receipts, 1134; Bulley (F. A.), Cases of Epidemic Cholera treated by Hot Water Applications, 1151; Burgess, Climate of Italy, 59; Burgess, Cazenave on Diseases of the Hair, 238; Carter (R. B.), Pathology and Treatment of Hysteria, 130; Chapman on Ulcers and Eruptions of the Leg, 565; Cheap, Nice, and Nourishing Cookery, 816; Christophers on Syphilis and Inoculation, 170; Cocks' Sea-weed Collector's Guide, 643; Cooper (White), on Sight, 458; Cotton (R. P.), on Consumption, 12; Coulson on Lithotomy and Lithotomy, 260; Cox on Homœopathy, 195; Cullen on the Climate of Sidmouth, 547; Cust (Hon. Lady), Invalid's Own Book, 815; Dalziel on Hysteria, 526; De Mynck on Contagion of Phthisis, 14; Dickson on Asylums for the Insane, 236; Egan on Syphilitic Diseases, 170; Epidemiological Society, Report on Small-pox and Vaccination, 590; Erichsen's Science and Art of Surgery, 1065; Forbes (Sir John), Memorandums made in Ireland, 595; Francis on Change of Climate, 641; Fuller on Rheumatism, Rheumatic Gout, and Scrofula, 168; Gosse's Naturalist's Rambles, 548; Gregory's Handbook of Inorganic Chemistry, 1014; Griffiths, Chemistry of the Four Seasons, 642; Guthrie's Surgery of the War in Portugal, etc., 815; Haden, Visiting List for 1854, 1151; Hannover on the Microscope, Goodsir's Translation, 674; Hayward, Permanent Cure of Reducible Hernia, 489; Headland on Action of Medicines, 15; Hinds on the Harmonies of Physical Science, 641; Hubert-Valleroux, Des Sourds-Muets, 543; Jones (H. B.), Du Bois Reymond's Animal Electricity, 63; Kahn, Atlas of the Formation of the Human Body, 397; Kennion, Medicinal Springs of Harrogate, 490; Knox's Manual of Human Anatomy, 39; Lawrance (R. M.), Electricity and Galvanism, 721; Ledwich's Practical Descriptive Anatomy, 304; Leidy, Translation of Gluge's Atlas of Pathological Histology, 459; Liebig's Handbook of Organic Analysis, 1013; Little on Deformities of the Human Frame, 568; Lyons on Primary Stages of Histogenesis and Histolysis, 835; McCormac's Modern Sanitary Economy, 569; Macilwain's Memoirs of John Abernethy, 1110; MacLise (Jos.), Surgical Anatomy, 1150; Mahony on Epidemic Cholera, 1039; Maisonneuve on Syphilis, 970; Markham, Translation of Skoda on Auscultation, 131; Marshall (John), Vaccination in Relation to Public Health, 546; Martin (W.), on Bronchotomy, 835; Mayne's Expository Lexicon, 969; Mémoires de la Société de Chirurgie de Paris, 131; Miller's Principles of Surgery, 969; Moseley, Sandgate as a Residence for Invalids, 835; Neligan on Diseases of the Skin, 542; Norris, Application of Iodine in Erysipelas, 108; Nunn on Inflammation of the Breast, 572; Parker on Painful Affections of Bone, 171; Part's Medical and Surgical Case Book, 776; Pearce's Every Mother's Book, 714; Peirce on Examination of Drugs, 642; Physician, Evening Thoughts by a, 643; Pravaz, Emploi Médical de l'Air Comprimé, 1038; Pulszky, White, Red, and Black, 460; Royle's Materia Medica and Therapeutics, 776; Scofield, Faraday's Lectures on Non-metallic Elements, 126; Shapter, Sanitary Measures and their Results, 237; Simpson (J. Y.) on Homœopathy, 396; Simpson (J. Y.), Modern Advancement of Practical Medicine and Surgery, *ib.*; Smith's Visiting List for 1853, 64; Snow, Continuous Molecular Changes, 484; Sophistry of Empiricism, 720; Southam, Introductory Lecture at Chatham Street School of Medicine, 1068; Spicer, Sights and Sounds, 462; Spurgin on Materia Medica, 207; Stanley and Evans, Report on the Ether Discovery, 106; Statham on Low Inflammations, 194; Stevens (W., M.D.), Treatment of Cholera, 548; Thomas's Modern Practice of Physic, 64; Tilt on Diseases of Women, 673; Toynbee on Artificial Membrana Tympani, 834; Traverse Oldfield, To Daimonion, 462; Trea-

- tise on Epidemic Cholera, 548; Turnbull (J., M.D.), Treatment of Consumption, 525; Valentin's Text Book of Physiology, translated by Brinton, 641, 1133; Van Oven, Decline of Life in Health and Disease, 1112; Walker (E. D.), Hints on Sea Bathing, 397; Walton's Operative Ophthalmic Surgery, 301; Ward (S. H.), Science of Health, 1112; What to observe at the Bedside and after Death, 39; Wilde's Aural Surgery, 835; Williams (Joseph), on the Lunacy Question, 236; Wittstein's Practical Pharmaceutical Chemistry, 1013
- Bile, Dr. Crisp on colouring matter of, 1114
- Billing, Dr. A., on Diseases of the Lungs and Heart, *rev.*, 160
- Bird, Dr. Golding, prolapsus of the vagina as a cause of fetid urine, 154; Urinary Deposits, *rev.*, 250; correspondence regarding Pulvermacher's chain, 316; on medical students, 1042
- Dr. James, What to observe in Medicine, *rev.*, 16; laws of epidemic and contagious diseases, 1020
- Birkett, Mr. John, chronic induration of mammae, 561
- Birth, Mr. R. U. West on hour of, 105
- Bismuth, trisnitrate of, adulterations of, 527
- Black, Dr. C., on vicarious excretion by the lungs, 354; Pathology of Pulmonary Mucous Membrane, *rev.*, 706; pathology of phthisis, 790
- Dr. James, on hospital abuses, 285; address at meeting of Lancashire branch, 613
- Blacklock, Mr. A., on Phosphate of Lime and Sulphur in Fever, *rev.*, 107
- Bladder, Mr. A. H. Paterson's case of sudden death from rupture of, 88; case of distension of, 128; irritability, in children, Dr. C. Fleming on, 216
- Blatin, M., on ointment of cowhage, 279
- Blennorrhagia, arbutus unedo in, 859
- Blodig, Dr., on amaurosis in heart disease, 241
- Blood, pus in, Mr. Gamgee on, 187, 1079; nature and functions of, Dr. Spurgin on, 207; formation of crystals from, 210, 1015; local effects of pus on, 355; Dr. Copland on pathological states of, 1041
- Bloodletting in visceral disease, Mr. Struthers on, 378
- Blot, Mr. H., diagnosis by auscultation of hydrocephalic foetus, 881
- Bloxam, Mr. J. C., closure of the foramen ovale, 129; physicians and general practitioners, 534; chloroform in midwifery, 701, 999; medical meteorology, 862; the Vaccination Act, 940, 1091
- Boa constrictor and family, 160
- Board of Health, statement of, 763
- Boileau de Castelnau, Dr., on instantaneous insanity, 40
- Boling, Dr., case of gastrotomy in tubal pregnancy, 215
- Bone, Mr. H. Lee on long continued pain in, 7; Mr. L. Parker on Treatment of Diseases of, *rev.*, 170; interstitial growth of, 176
- Books received, 74, 114, 226, 265, 312, 387, 448, 476, 496, 516, 536, 556, 658, 696, 716, 764, 912, 958, 960, 1097
- Botany, study of, 96
- Bowling, Mr. J. P., abscess of caecum in an opium eater, 150
- Bowman, Mr. W., on two needles in operations on the eye, 551
- Brain, Dr. H. Sandwith on opium in diseased states of in fever, 5; cases of disease of, 100; recovery after loss of portions of, 375, 610; Dr. A. W. Barclay on fatal cases of disease of, 725; syphilitic disease of, 994; Dr. Semple on diseases of, 1051
- Brainard, Dr., treatment of vascular tumours by injections of lactate of iron, 1085
- Branch system, capabilities of, 268; meetings, 606; Dr. McIntyre on organisation of, 677. See ASSOCIATION.
- Breasts, Dr. Cormack on galactagogue and emmenagogue effects of warm and stimulating applications to, 254; acute hypertrophy of, 305; cystic sarcoma removed by operation, 465; Mr. Birkett on chronic induration of, 561; Mr. Nunn, on Inflammation of, *rev.*, 572
- Breech presentations, Dr. C. Bell on, 648; Mr. R. U. West on, 605
- Bright, Dr. R. and Holloway's ointment, 520
